## **IMPORTANT NOTICE**

Texas Instruments (TI) reserves the right to make changes to its products or to discontinue any semiconductor product or service without notice, and advises its customers to obtain the latest version of relevant information to verify, before placing orders, that the information being relied on is current.

TI warrants performance of its semiconductor products and related software to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

Certain applications using semiconductor products may involve potential risks of death, personal injury, or severe property or environmental damage ("Critical Applications").

**TI SEMICONDUCTOR PRODUCTS ARE NOT DESIGNED, INTENDED, AUTHORIZED, OR WARRANTED TO BE SUITABLE FOR USE IN LIFE-SUPPORT APPLICATIONS, DEVICES OR SYSTEMS OR OTHER CRITICAL APPLICATIONS.**

Inclusion of TI products in such applications is understood to be fully at the risk of the customer. Use of TI products in such applications requires the written approval of an appropriate TI officer. Questions concerning potential risk applications should be directed to TI through a local SC sales office.

In order to minimize risks associated with the customer's applications, adequate design and operating safeguards should be provided by the customer to minimize inherent or procedural hazards.

TI assumes no liability for applications assistance, customer product design, software performance, or infringement of patents or services described herein. Nor does TI warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used.

**Reader Response Card: TMS320C54x DSP Reference Set, Volume 4: Applications Guide**

*Texas Instruments wants to provide you with the best documentation possible. Please help us meet this goal by answering these questions and returning this card.*

What is your primary use for the information in this manual?

- Designing 'C54x-based hardware
- Designing 'C54x-based software

How have you used this manual?

- To look up specific information when needed (as a reference)
- To read chapters about subjects of interest
- To read from front to back before using the information

Please describe any mistakes or unclear information in this manual (include page numbers).

\_\_\_\_\_

\_\_\_\_\_

\_\_\_\_\_

\_\_\_\_\_

Which topics should be described in greater detail?

\_\_\_\_\_

\_\_\_\_\_

\_\_\_\_\_

Please list topics that were difficult to find, and why (for example, the topic was not in a logical location).

\_\_\_\_\_

\_\_\_\_\_

\_\_\_\_\_

Please list any other suggestions for improving this book.

\_\_\_\_\_

\_\_\_\_\_

\_\_\_\_\_

Name \_\_\_\_\_ Title \_\_\_\_\_

Company \_\_\_\_\_

Address \_\_\_\_\_

City \_\_\_\_\_ State \_\_\_\_\_ Zip/Country \_\_\_\_\_

Phone number \_\_\_\_\_

## ***About This Manual***

The purpose of this book is to present integrated solutions for typical TMS320C54x design issues. It combines a description of specific programming topics with code examples. The text discusses basic programming topics for the '54x digital signal processor (DSP). The code examples were created and tested in real time using the '54x evaluation module (EVM) as a platform. You may use these examples in developing your applications.

## ***How to Use This Manual***

The book is divided into two parts: topic information, provided in Chapters 1–9, and complete code examples, provided in Chapter 10.

- Topic information, Chapters 1–9: These chapters give you a framework of knowledge for programming the '54x. Before creating code, beginners may want to read these chapters entirely to understand why these issues must be addressed in certain ways. Advanced users may want to read only the topics relevant to specific code applications.
- Complete code examples, Chapter 10: These examples elaborate on the code provided in Chapters 1–9. This code has been tested and can be run as is.

## ***Notational Conventions***

This document uses the following conventions.

- Program listings and program examples are shown in a special font.

Here is a sample program listing:

```
STL      A, *AR1+           ; Int_RAM(I)=0
RSBX    INTM                ; Globally enable interrupts
B       MAIN_PG            ; Return to foreground program
```

- Throughout this book, the notation '54x refers to the TMS320C54x and the TMS320VC54x. The notations '541, '542, etc., refer to the TMS320C541, TMS320C542, etc. The notation 'LC548 refers to the TMS320LC548.

**Related Documentation from Texas Instruments**

The following books describe the '54x and related support tools. To obtain a copy of any of these TI documents, call the Texas Instruments Literature Response Center at (800) 477-8924. When ordering, please identify the book by its title and literature number.

**TMS320C54x DSP Reference Set** (literature number SPRU210) is composed of four volumes of information, each with its own literature number for individual ordering.

**TMS320C54x DSP Reference Set, Volume 1: CPU and Peripherals** (literature number SPRU131) describes the TMS320C54x 16-bit, fixed-point, general-purpose digital signal processors. Covered are its architecture, internal register structure, data and program addressing, the instruction pipeline, DMA, and on-chip peripherals. Also includes development support information, parts lists, and design considerations for using the XDS510 emulator.

**TMS320C54x DSP Reference Set, Volume 2: Mnemonic Instruction Set** (literature number SPRU172) describes the TMS320C54x digital signal processor mnemonic instructions individually. Also includes a summary of instruction set classes and cycles.

**TMS320C54x DSP Reference Set, Volume 3: Algebraic Instruction Set** (literature number SPRU179) describes the TMS320C54x digital signal processor algebraic instructions individually. Also includes a summary of instruction set classes and cycles.

**TMS320C54x DSP Reference Set, Volume 4: Applications Guide** (literature number SPRU173) describes software and hardware applications for the TMS320C54x digital signal processor. Also includes development support information, parts lists, and design considerations for using the XDS510 emulator.

**TMS320C54x, TMS320LC54x, TMS320VC54x Fixed-Point Digital Signal Processors** (literature number SPRS039) data sheet contains the electrical and timing specifications for these devices, as well as signal descriptions and pinouts for all of the available packages.

**TMS320C54x Assembly Language Tools User's Guide** (literature number SPRU102) describes the assembly language tools (assembler, linker, and other tools used to develop assembly language code), assembler directives, macros, common object file format, and symbolic debugging directives for the 'C54x generation of devices.

**TMS320C5xx C Source Debugger User's Guide** (literature number SPRU099) tells you how to invoke the 'C54x emulator, EVM, and simulator versions of the C source debugger interface. This book discusses various aspects of the debugger interface, including window management, command entry, code execution, data management, and breakpoints. It also includes a tutorial that introduces basic debugger functionality.

**TMS320C54x Code Generation Tools Getting Started Guide** (literature number SPRU147) describes how to install the TMS320C54x assembly language tools and the C compiler for the 'C54x devices. The installation for MS-DOS™, OS/2™, SunOS™, Solaris™, and HP-UX™ 9.0x systems is covered.

**TMS320C54x Evaluation Module Technical Reference** (literature number SPRU135) describes the 'C54x EVM, its features, design details and external interfaces.

**TMS320C54x Optimizing C Compiler User's Guide** (literature number SPRU103) describes the 'C54x C compiler. This C compiler accepts ANSI standard C source code and produces TMS320 assembly language source code for the 'C54x generation of devices.

**TMS320C54x Simulator Getting Started** (literature number SPRU137) describes how to install the TMS320C54x simulator and the C source debugger for the 'C54x. The installation for MS-DOS™, PC-DOS™, SunOS™, Solaris™, and HP-UX™ systems is covered.

**TMS320 Third-Party Support Reference Guide** (literature number SPRU052) alphabetically lists over 100 third parties that provide various products that serve the family of '320 digital signal processors. A myriad of products and applications are offered—software and hardware development tools, speech recognition, image processing, noise cancellation, modems, etc.

**TMS320 DSP Development Support Reference Guide** (literature number SPRU011) describes the TMS320 family of digital signal processors and the tools that support these devices. Included are code-generation tools (compilers, assemblers, linkers, etc.) and system integration and debug tools (simulators, emulators, evaluation modules, etc.). Also covered are available documentation, seminars, the university program, and factory repair and exchange.

# Contents

---

---

---

<b>1</b>	<b>Introduction</b> .....	<b>1-1</b>
	<i>Presents an introduction to DSP systems, which consist of a DSP, optional external memory, and an analog front end. Describes the architecture of a typical DSP and an EVM.</i>	
1.1	DSP Overview .....	1-2
1.2	'54x Evaluation Module (EVM) Overview .....	1-3
1.3	Memory Interface .....	1-4
1.4	'54x EVM External Memory Interface .....	1-6
<b>2</b>	<b>System Start-Up</b> .....	<b>2-1</b>
	<i>Presents typical options when using on-chip ROM, external 16-bit memory (EPROM), or bootloading from an 8-bit EPROM. Describes start-up conditions and initialization.</i>	
2.1	On-Chip ROM/External 16-Bit EPROM .....	2-2
2.2	Processor Initialization .....	2-3
<b>3</b>	<b>Analog I/O</b> .....	<b>3-1</b>
	<i>Describes the most common means by which data goes to and from the DSP. Discusses initialization of serial ports and the process of acquiring and transmitting data using interrupt service routines (ISRs).</i>	
3.1	Synchronous Serial Port Devices .....	3-2
3.2	TLC320AC01 Analog Interface Circuit .....	3-5
3.3	Software Stack .....	3-19
3.4	Context Switching .....	3-20
3.5	Interrupt Handling .....	3-22
3.6	Interrupt Priority .....	3-25
3.7	Circular Addressing .....	3-26
3.8	Buffered Serial Port .....	3-28
<b>4</b>	<b>Signal Processing</b> .....	<b>4-1</b>
	<i>Discusses digital filters that use both fixed and adaptive coefficients and real fast Fourier transforms.</i>	
4.1	Finite Impulse Response (FIR) Filters .....	4-2
4.2	Infinite Impulse Response (IIR) Filters .....	4-9
4.3	Adaptive Filtering .....	4-12
4.4	Fast Fourier Transforms (FFTs) .....	4-19
	4.4.1 Memory Allocation for Real FFT Example .....	4-19
	4.4.2 Real FFT Example .....	4-22

<b>5</b>	<b>Resource Management</b> .....	<b>5-1</b>
	<i>Discusses the on- versus off-chip memory and how to handle requirements for more than 64K words of memory.</i>	
5.1	Memory Allocation .....	5-2
5.2	Overlay Management .....	5-5
5.3	Memory-to-Memory Moves .....	5-6
5.4	Power Management .....	5-8
<b>6</b>	<b>Arithmetic and Logical Operations</b> .....	<b>6-1</b>
	<i>Takes a look at both single- and extended-precision operations, for both fixed-point and floating-point examples. Discusses methods of bit manipulation and packing/unpacking data.</i>	
6.1	Division and Modulus Algorithm .....	6-2
6.2	Sines and Cosines .....	6-9
6.3	Square Roots .....	6-14
6.4	Extended-Precision Arithmetic .....	6-17
	6.4.1 Addition and Subtraction .....	6-18
	6.4.2 Multiplication .....	6-21
6.5	Floating-Point Arithmetic .....	6-24
6.6	Logical Operations .....	6-43
<b>7</b>	<b>Application-Specific Examples</b> .....	<b>7-1</b>
	<i>Describes applications using codebook search for speech coding and Viterbi decoding for telecommunications.</i>	
7.1	Codebook Search for Excitation Signal in Speech Coding .....	7-2
7.2	Viterbi Algorithm for Channel Decoding .....	7-5
<b>8</b>	<b>Bootloader</b> .....	<b>8-1</b>
	<i>Describes the process of loading programs received from the host, EPROMs, or other memory devices. Discusses various methods of bootloading and when to use them.</i>	
8.1	Boot Mode Selection .....	8-2
8.2	Host Port Interface (HPI) Boot Loading Sequence .....	8-4
8.3	16-Bit/8-Bit Parallel Boot .....	8-5
8.4	I/O Boot .....	8-8
8.5	Standard Serial Boot .....	8-10
8.6	Warm Boot .....	8-12
<b>9</b>	<b>Host–Target Communication</b> .....	<b>9-1</b>
	<i>Describes the communication process and the registers used in transmission between the '54x EVM and its host.</i>	
9.1	Communication Channels .....	9-2
9.2	Handshake and Data Transfer .....	9-6

<b>10</b>	<b>Application Code Examples</b> .....	<b>10-1</b>
	<i>Provides code examples from start-up initialization to signal processing developed for real-time operation on the '54x EVM.</i>	
10.1	Running the Applications .....	10-2
10.2	Application Code .....	10-4
<b>A</b>	<b>Design Considerations for Using XDS510 Emulator</b> .....	<b>A-1</b>
	<i>Describes the JTAG emulator cable and how to construct a 14-pin connector on your target system and how to connect the target system to the emulator.</i>	
A.1	Designing Your Target System's Emulator Connector (14-Pin Header) .....	A-2
A.2	Bus Protocol .....	A-4
A.3	Emulator Cable Pod .....	A-5
A.4	Emulator Cable Pod Signal Timing .....	A-6
A.5	Emulation Timing Calculations .....	A-7
A.6	Connections Between the Emulator and the Target System .....	A-10
	A.6.1 Buffering Signals .....	A-10
	A.6.2 Using a Target-System Clock .....	A-12
	A.6.3 Configuring Multiple Processors .....	A-13
A.7	Physical Dimensions for the 14-Pin Emulator Connector .....	A-14
A.8	Emulation Design Considerations .....	A-16
	A.8.1 Using Scan Path Linkers .....	A-16
	A.8.2 Emulation Timing Calculations for a Scan Path Linker (SPL) .....	A-18
	A.8.3 Using Emulation Pins .....	A-20
	A.8.4 Performing Diagnostic Applications .....	A-24
<b>B</b>	<b>Development Support and Part Order Information</b> .....	<b>B-1</b>
	<i>Provides device part numbers and support tool ordering information for the TMS320C54x and development support information available from TI and third-party vendors.</i>	
B.1	Development Support .....	B-2
	B.1.1 Development Tools .....	B-2
	B.1.2 Third-Party Support .....	B-3
	B.1.3 Technical Training Organization (TTO) TMS320 Workshops .....	B-4
	B.1.4 Assistance .....	B-4
B.2	Part Order Information .....	B-5
	B.2.1 Device and Development Support Tool Nomenclature Prefixes .....	B-5
	B.2.2 Device Nomenclature .....	B-6
	B.2.3 Development Support Tools .....	B-7
<b>C</b>	<b>Glossary</b> .....	<b>C-1</b>
	<i>Defines terms and abbreviations used throughout this book.</i>

# Introduction

---

---

---

---

The TMS320C54x is a fixed-point digital signal processor (DSP) in the TMS320 family. It provides many options for the design of telecommunication and wireless applications. It executes 50 million instructions per second (MIPS), providing high performance, low power consumption, and cost effectiveness.

The code examples in this book were tested in real time using a '54x Evaluation Module (EVM) platform. This chapter introduces you to DSP and EVM architecture and describes the '54x memory interface mechanism and the EVM's interface with memory devices. Since the '54x EVM contains a '541 DSP, the chapter discusses the '541 specifically.

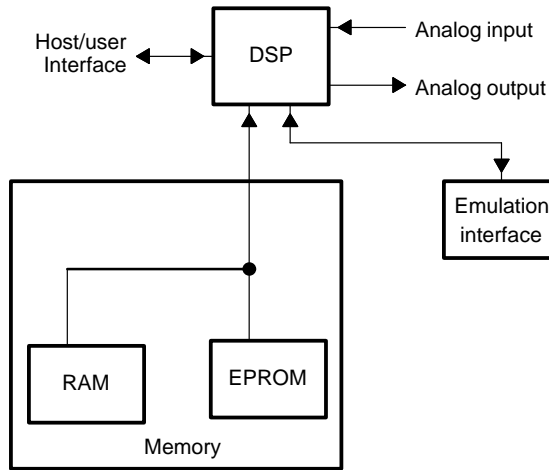

<b>Topic</b>	<b>Page</b>
1.1 DSP Overview .....	1-2
1.2 '54x Evaluation Module (EVM) Overview .....	1-3
1.3 Memory Interface .....	1-4
1.4 '54x EVM External Memory Interface .....	1-6

### 1.1 DSP Overview

The block diagram in Figure 1–1 represents a typical DSP system. It uses an analog interface, where an input signal is digitized and processed by the DSP and has an output terminal. The RAM and EPROM blocks make up the system’s memory. These blocks sometimes replace with DSP on-chip memory. For a stand-alone system, an EPROM bootloads the code during system power-up. The emulation interface can access the ’54x high-level language debuggers, factory-installed tests, and field diagnostics. The host can download program files or data through the emulation port. The host interface provides buffering, host I/O decode, and access control.

Figure 1–1. Typical DSP System

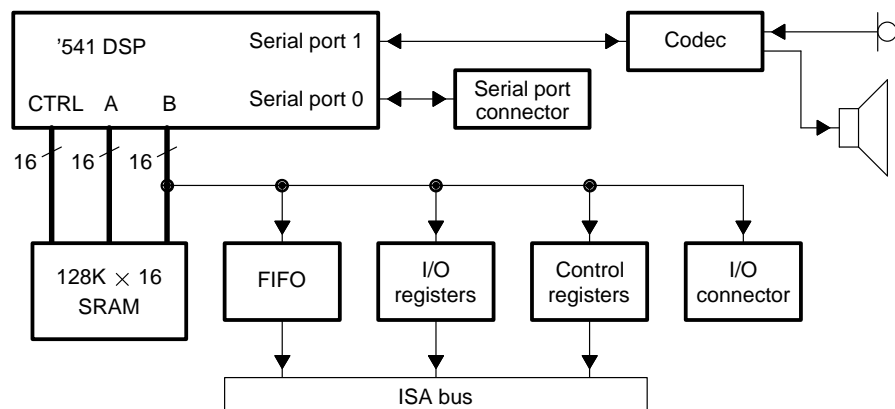

## 1.2 '54x Evaluation Module (EVM) Overview

The '54x EVM is a PC/AT™ plug-in half-card that consists of a '541 DSP, 128K × 16 words of fast SRAM, and a TLC320AC01 analog interface chip (AIC). It also includes a programmer interface and a mouse-driven, window-oriented C source debugger. It provides a platform for using real-time device evaluation, benchmarking, and system debugging to design embedded systems.

The EVM has all common software debugging features, including breakpoint, modify, load, and watch. User-defined windows can be set up to view device parameters. The '54x EVM comes with a full assembler/linker package and an expansion port for interfacing to peripherals. Other hosts, systems, and target boards can communicate with the EVM using the serial port connector, provided on the board. The EVM allows you to prototype application software and hardware. The example code provided in chapter 10 uses '54x EVM as the hardware platform along with a host interface and demonstrates the various applications using signal processing techniques.

Figure 1–2 shows the configuration of the '54x EVM. It interfaces to 128K words of zero wait-state static RAM. The EVM includes 64K words of zero wait-state program memory and 64K words of zero wait-state data memory. An external I/O interface supports 16 parallel I/O ports and a serial port. The host-target communication system provides a simple means to pass data between the target and host during real-time operation. The two channels, A and B, are single, 16-bit bidirectional registers, mapped into two I/O port locations. Channel B has a 64-word deep FIFO buffer. The analog interface circuit (AIC) interfaces to the '541 serial port. The codec is a TLC320AC01 AIC that provides a 14-bit A/D and D/A interface with 16 bits of dynamic range, and sampling rates up to 43.2 kHz. Two RCA connectors provide analog input and output for 'AC01.

Figure 1–2. Block Diagram of a '54x EVM

### 1.3 Memory Interface

The '54x has several types of memory interfaces. Each interface contains a 16-bit address bus and 16-bit data bus signal lines. These transfer information and control interface operation. All of the interfaces are independent of one another, and different operations can be performed simultaneously on each interface.

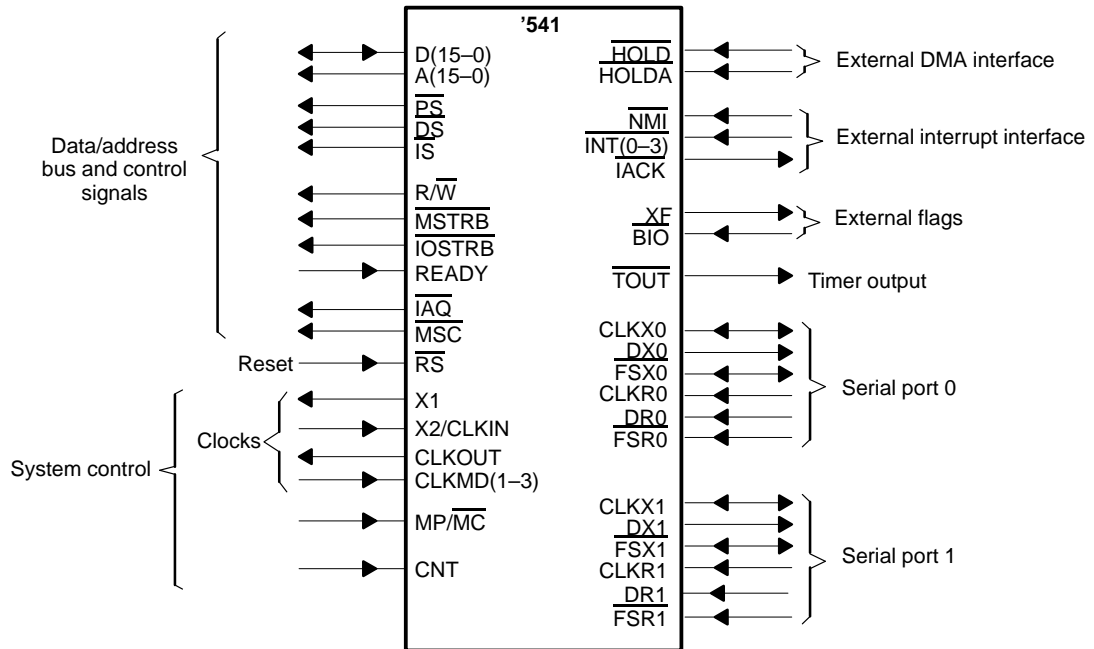

The external direct memory access (DMA) interface lets external devices cause the processor to give up the bus and control signals for DMA. The  $\overline{\text{MSTRB}}$  signal is activated for program and memory accesses, and the  $\overline{\text{IOSTRB}}$  signal is used for transactions with I/O ports (PORTR and PORTW instructions). The  $\text{R}/\overline{\text{W}}$  signal controls the direction of accesses. The external ready input signal (READY) and the software-programmable wait-state generators allow the processor to interface with memory and I/O devices of varying speeds.

Two signals,  $\overline{\text{HOLD}}$  and  $\overline{\text{HOLDA}}$ , allow an external device to take control of the processor's buses. The processor acknowledges receiving a  $\overline{\text{HOLD}}$  signal from an external device by bringing  $\overline{\text{HOLDA}}$  low. The  $\overline{\text{RS}}$  signal initializes the internal '541 logic and executes the system-initialization software. The  $\overline{\text{PS}}$ ,  $\overline{\text{DS}}$ , and  $\overline{\text{I/O}}$  select signals are used to select any external program, data, or I/O access. The connection of X1 and X2/CLKIN determines the clock source that drives the clock generator. The clock mode that operates the clock generator is determined by the CLKMD(1–3) signals.

Figure 1–3 shows the external interfaces on the '541. The device contains two independent bidirectional serial ports: serial port 0 and serial port 1. The analog interface circuit interfaces directly to the serial ports of the '541. The external flag,  $\overline{\text{BIO}}$ , is used to monitor the status of the peripheral devices. The XF pin signals external devices via software. The '541 has four external, maskable user interrupts that external devices can use to interrupt the processor and one external, nonmaskable interrupt (NMI). These provide a convenient means to perform periodic I/O or other functions.

The '541 can be interfaced with EPROMs and static RAMs. The speed, cost, and power limitations imposed by an application determine the selection of memory device. If speed and maximum throughput are important, the '541 can run with no wait states. In this case, memory accesses are performed in a single machine cycle. Slower memories can be accessed by introducing an appropriate number of wait states or slowing down the system clock.

Figure 1-3. External Interfaces on the '541

## 1.4 '54x EVM External Memory Interface

The '54x EVM includes 64K words of zero wait-state program memory and 64K words of zero wait-state data memory, providing a total of 128K words of external memory. The  $\overline{PS}$  line controls accesses to data and program memory. Each time the DSP accesses external program memory, the  $\overline{PS}$  line goes low, driving the A16 address line low and forcing access to memory locations 00000h – 0FFFFh. Data memory accesses have no effect on the  $\overline{PS}$  line. During data memory accesses, the  $\overline{PS}$  line remains high. This means that the EVM accesses memory locations from 100000h – 1FFFFh. These accesses are tabulated in the truth table below.

Access	$\overline{MSTRB}$	$\overline{PS}$	$\overline{DS}$
Program	0	0	1
Data	0	1	0
No access	1	1	1

Figure 1–4 shows a diagram of program/data memory interfaces for the EVM.

# System Start-Up

---

---

---

---

To successfully power up a system, you must have a clear understanding of reset signals, clock modes and sources, memory interfaces with and without wait states, and bank switching. Common methods to start up a program include using on-chip ROM, external 16-bit EPROM, and bootloading from an 8-bit EPROM. This chapter examines these start-up methods and parameters and gives examples of initialization software.

<b>Topic</b>	<b>Page</b>
<b>2.1 On-Chip ROM/External 16-Bit EPROM .....</b>	<b>2-2</b>
<b>2.2 Processor Initialization .....</b>	<b>2-3</b>

## 2.1 On-Chip ROM/External 16-Bit EPROM

The '54x program memory space can reside either on- or off-chip. On-chip memory can include RAM, ROM, and external SRAM; off-chip memory can include 16-bit EPROM. There are two common methods to execute a program: running from memory (which uses on-chip ROM or 16-bit external EPROM) or using the bootloader either serially or in parallel from a 16- or an 8-bit EPROM.

The system can run using a 16-bit external EPROM or on-chip ROM. With on-chip ROM, internal memory is enabled. The EVM uses 128K words of external memory, which includes 64K words each of program and data memory. If a program resides in the external memory space, the program space includes part of the 64K of program memory. The EVM has external SRAM that can emulate either on-chip ROM or external EPROM. Executing the code from on-chip ROM requires no wait states, whereas executing from external EPROM requires some wait states, depending upon the speed of the DSP and the speed of the EPROM. In either case, the program starts executing from the reset vector, FF80h.

Program memory in on-chip ROM is configured internally, since the processor is in microcomputer mode when the  $MP/\overline{MC}$  pin is low. For 16-bit EPROM, the program space is external. The processor is configured in microprocessor mode when  $MP/\overline{MC}$  is high.

## 2.2 Processor Initialization

At power-up, the state of the '54x processor is partially defined, since all the bits in both status control registers are established. Thus, the processor is in a predefined condition at reset. Some of the conditions in these registers can be changed, depending upon the system configuration and the application. The reset signal puts the processor in a known state. In a typical DSP system, the processor must be initialized for proper execution of an application.

Starting up the system from on-chip ROM or 16-bit EPROM is done by resetting the processor. In both cases, the processor is reset by applying a low level to the  $\overline{RS}$  pin. Reset causes the processor to fetch the reset vector. Upon reset, the IPTR bits of the PMST register are all set to 1, mapping the vectors to page 511 in program memory space. This means that the reset vector always resides at program memory location 0FF80h. This location usually contains a branch instruction to direct program execution to the system initialization routine.

After a reset, the processor initializes the following internal functions:

- Stack pointer (SP)
- Memory-mapped peripheral control registers (SWWSR and BSCR)
- Status registers (ST0 and ST1)
- Control register (PMST)

Some of the reset bits in the status and control registers can be changed during initialization. The '54x has a software stack and the stack pointer must be initialized. The data page pointer, which is initialized to page 0 during reset, must also be configured during initialization. The predefined and the remaining bits in ST0, ST1, and PMST are initialized so that the processor starts executing the code from a defined state.

Software wait-state generators interface external memory devices to the processor. Programmable bank switching determines the bank size. The software wait-state register (SWWSR) and the bank-switching control register (BCSR) are initialized.

Example 2–1 initializes the vector table. Example 2–2, on page 2-6, initializes the '54x, where the processor branches to main\_start upon reset.

# Analog I/O

---

---

---

---

Most DSP systems transfer data through peripherals. These peripherals include parallel and serial ports. This chapter describes how the serial ports are initialized and how the TLC320AC01 ('AC01) analog interface circuit (AIC) interfaces to the '54x serial port. This chapter also describes the various issues involved such as stack, context switching, interrupt priorities, and different addressing modes for collecting the samples during the interrupt processing.

### 3.1 Synchronous Serial Port Devices

Several '54x devices implement a variety of types of flexible serial port interfaces. These serial port interfaces provide full duplex, bidirectional, communication with serial devices such as codecs, serial analog to digital (A/D) converters, and other serial systems. The serial port interface signals are directly compatible with many industry-standard codecs and other serial devices. The serial port may also be used for interprocessor communication in multiprocessing applications. When the serial ports are in reset, the device can be configured to shut off the serial port clocks. This allows the device to run in a low-power mode of operation.

Three signals are necessary to connect the '54x to the serial port, as shown in Figure 3–1. On the transmitting device, the transmit data signal (DX) sends the data, the transmit frame synchronization signal (FSX) initiates the transfer at the beginning of the packet, and the transmit clock signal (CLKX) clocks the bit transfer.

The corresponding pins on the receiving device are the received serial data signal (DR), the receive frame synchronization signal (FSR) and, the receive clock signal (CLKR), respectively. At reset, CLKX, CLKR, DR, FSX, and FSR become inputs and DX is set for high impedance. Figure 3–1 shows the '54x interface to an 'AC01 that uses the serial port to transfer the data to and from the DSP. The SCLK signal clocks the serial data into and out of the device.

Figure 3–1. Interfacing a TLC320AC01C AIC to the '54x

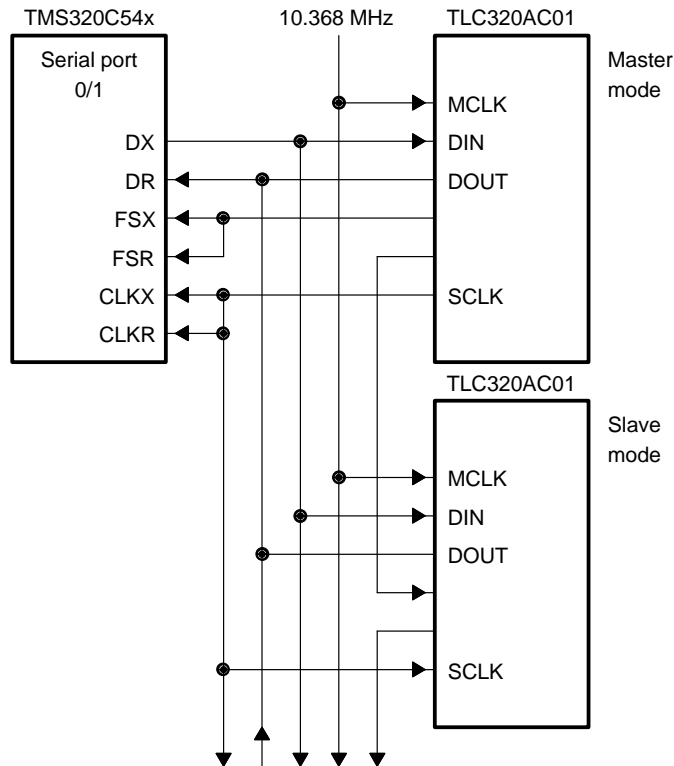

Figure 3–2 shows the master and slave-to-DSP interface. In the master-slave mode, the master 'AC01, generates its own shift clock and frame sync signals and generates all delayed frame-sync signals to support slave devices. The slave receives the shift clock and frame-sync signals from the master device.

Figure 3–2. Master- and Slave-to-'54x Interfaces

The serial port operates through three memory-mapped registers: the serial port control register (SPC), the data transmit register (DXR), and the data receive register (DRR). The configuration of the serial port is changed by writing to the SPC register. The system configuration is as follows:

- Word length: The serial port must be programmed to use 16-bit data, since communications between the 'AC01 AIC and the host DSP use 16 bits. This means clearing the format bit, FO, to a logic 0.
- Frame synchronization: The system operates in burst mode with frame synchronization signals generated externally by the 'AC01. This means the frame synchronization mode bit, FSM, must be set to a logic 1. A frame sync pulse is required on the frame sync transmit and receive pins (FSX and FSR, respectively) for the transmission and reception of every word.

It also means that the FSX pin has to be configured as an input pin by clearing the transmit mode bit, TXM, to a logic 0.

- Clock: The clock is generated externally by the 'AC01 and is supplied to the DSP on the CLKX pin. This means clearing the clock mode bit, MCM, to a logic 0.

To reset the serial port, two writes to the SPC register must occur. The first must write 0s to the transmit reset (XRST) and receive reset (RRST) bits and the desired configuration to all the other bits. The second must write 1s to the XRST and RRST bits and write the desired configuration to all the other bits. The SPC register is written as 0000 0000 1100 1000 to pull the serial port out of reset. This is shown in Example 3-1 on page 3-7.

### 3.2 TLC320AC01 Analog Interface Circuit

The 'AC01 is an audio-band processor. It integrates a band-pass switched-capacitor antialiasing input filter, 14-bit A/D and D/A converters, a low-pass switched-capacitor output reconstruction filter,  $\sin x/x$  compensation, and a serial port for data and control transfers. The A/D and D/A channels operate synchronously, and data is transferred in 2s-complement format. It has nine internal registers that can be programmed for an application.

There are three basic modes of operation:

- 1) Stand-alone analog interface mode: The 'AC01 generates the shift clock and frame synchronization signals for data transfers; it is the only AIC used.
- 2) Master-slave mode: One 'AC01 serves as the master, generating the master shift clock and frame synchronization signals; the other 'AC01s serve as slaves.
- 3) Linear codec mode: The shift clock and frame synchronization signals are externally generated by the host.

Software control of the AIC allows you to program the sampling frequency, cut-off frequencies for the low- and high-pass filters, and analog input and output gains at any time. No programming is needed when the default values of the 'AC01 are satisfactory.

Data transfers between the DSP and the 'AC01 are categorized as primary and secondary serial communications. During primary communication, the 14 most significant bits (MSBs), bits 2 through 15, specify sample data. If the two least significant bits (LSBs), bits 1 and 0, are 11, a subsequent 16 bits of control information is received by the 'AC01 as part of the secondary serial communication interval. This control information programs one of the nine internal registers. During the secondary communication interval, the bits transmitted to the 'AC01 are defined as follows:

- Bits 15 and 14, which control phase shifting in certain applications, are usually 0s.
- Bit 13 decides whether the data is written to or read from a register.
- Bits 12 through 8 define the address of the register to be programmed.
- Bits 7 through 0 contain the data to be stored in a register for write operations.

The bits received from the 'AC01 during the secondary communication interval are 0s for bits 15 through 8, and the value of the register data for bits 7 through 0.

The three programs that follow show the use of the 'AC01 in different circumstances: Example 3–1 assumes that the user is satisfied with the default configuration of the 'AC01 and proceeds to receive and send data, Example 3–2 on page 3-12 shows how to program the 'AC01 for a particular configuration before data transfer, and Example 3–3 on page 3-17 demonstrates serial communications while in a master-slave configuration. All three programs consist of a main routine which, apart from initializing the serial port and the interrupt, also resets the 'AC01.

Example 3–1 initiates a reset of the 'AC01, initializes the serial port, and sets up interrupts. To reset the 'AC01 properly, it must be held in reset for at least one MCLK cycle. With the 'AC01 operating at 10.368 MHz, one MCLK cycle equals 96.45 ns. In all the examples, the total time spent between initiating a reset and pulling the 'AC01 out of reset is 12 cycles. For a '54x DSP operating at 40 MHz, one cycle is 25 ns. This means that the 'AC01 spends 300 ns in reset. This is roughly three times the specification's recommended value and is safe, since it allows a proper reset.

If a 50-MHz DSP is used, one cycle equals 20 ns; the same code keeps the 'AC01 in reset for 240 ns. This is also safe, since it is approximately 2.5 times the specification's recommended value.

The 'AC01 can operate at a minimum clock frequency of 5.184 MHz. This implies that it must be held in reset for at least one MCLK cycle, or 192.9 ns. Assuming a processor speed of 50 MHz, the 'AC01 spends 12 cycles multiplied by 20 ns = 240 ns in reset.

A safe margin holds the 'AC01 in reset for at least twice the specification's recommended time. To allow the necessary time in reset, use a dedicated timer function or insert useful instructions to fill the time slot. After the 'AC01 is reset, the main program sits in a loop, waiting for a serial port interrupt.

Example 3–1 initializes the serial port and uses the default initialization of the 'AC01, which is in the master mode and transfers the data upon a receive interrupt. It is not necessary to initiate a secondary communication interval to program the 'AC01. The serial port is configured between the cycles that the AIC is in reset.

**Example 3–1. Default Initialization of 'AC01**

Example 3–2 on page 3-12 demonstrates initiation of a secondary communication interval for programming the 'AC01. The configuration of the 'AC01 can be changed via its nine internal registers. To understand this, consider registers 1 and 2 in the 'AC01.

The data content of register 1, also referred to as the register A, determines the divisions of the master clock frequency that produce the internal filter clock, FCLK. The default value of this register is 18 (decimal). The filter clock frequency is calculated using the equation:

$$\text{FCLK frequency} = \text{master clock frequency} / (\text{register A contents} \times 2)$$

This means that for an MCLK of 10.368 MHz, the default value of the filter clock frequency is

$$\text{FCLK} = 288 \text{ kHz}$$

This FCLK determines the –3 dB corner frequency of the low-pass filter which is given by:

$$f_{LP} = \text{FCLK}/40$$

The default value of  $f_{LP}$  is equal to 7.2 kHz.

The data content of register 2 of the 'AC01, also referred to as register B, determines the division of FCLK to generate the conversion clock, and is given by the equation:

$$\text{Conversion frequency} = \text{FCLK}/(\text{register B contents})$$

The default value of register B is equal to 18 (decimal). Hence, the default value of the conversion (sampling) frequency is equal to:

$$288 \text{ kHz} / 18 = 16 \text{ kHz}$$

This register also determines the –3 dB corner frequency of the high-pass filter, which is given by:

$$f_{HP} = \text{sampling frequency}/200$$

Hence, the default value of  $f_{HP}$  is equal to 80 Hz.

For a system that processes speech signals, the following parameters are desirable:

$$\text{Sampling frequency } f_s = 8.0 \text{ kHz}$$

$$\text{Low-pass filter corner frequency, } f_{LP} = 3.6 \text{ kHz}$$

Assume that the 'AC01 uses a master clock frequency, MCLK, of 10.368 MHz. The 'AC01's parameters are:

$$f_{LP} = FCLK/40 \text{ gives } FCLK = 144 \text{ kHz}$$

$$FCLK = MCLK/(\text{register A} \times 2) \text{ gives register A} = 36 \text{ (decimal)}$$

$$f_s = FCLK/B \text{ gives register B} = 18 \text{ (decimal)}$$

This also means that with the specified sampling frequency, the  $-3$  dB corner frequency of the high-pass filter changes to  $8.0 \text{ kHz} / 200 = 48 \text{ Hz}$ .

After the 'AC01 has been reset in the main program, it makes a call to the routine `wrt_cnfg`, which programs the new values of registers A and B as calculated above. To prevent the occurrence of an interrupt while programming the 'AC01, `wrt_cnfg` disables all interrupts until the end of programming. After each word has been sent to the serial port, the code waits for the data to be copied from the data transmit register to the transmit shift register before it sends the next data. After the 'AC01 has been programmed, the main routine waits for an interrupt. The service routines that transfer data between the memory buffers and the serial port transmit and receive registers remain the same.

*Example 3–2. Initiation of a Secondary Communication Interval for Programming the 'AC01*

Example 3–3 on page 3-17 uses two 'AC01s in master-slave configuration. After the 'AC01s have been reset, the Ac01s make a call to the routine `wrt_cfg`. This routine programs the low- and high-pass filter cutoff frequencies, the number of slave devices attached, and sets up the frame-sync delay register. During the programming mode, the master and its slaves are programmed with the same control information. The last register programmed is frame-sync delay, which determines the lag between the frame-sync and delayed frame-sync signals. The minimum value for the frame-sync delay register is 18 (decimal). This is because every data transfer requires 16 clock periods, and the output data, DOUT, is placed in the high-impedance state on the 17th rising edge of the clock.

Example 3–3 uses a minimum value of 18, which means that the time delay between the frame sync and the delayed frame sync is equal to 18 multiplied by the period of SCLK. With  $SCLK = 2.592$  MHz based on an MCLK of 10.368 MHz, the time delay is  $6.94\mu\text{s}$ . The hardware schematic indicates that the delayed frame-sync signal from the master is the frame-sync signal for the slave. The master, therefore, generates a frame-sync signal for itself and a delayed frame-sync signal for its slave. It then synchronizes the host serial port for data transfers to itself and its slaves. All interrupts on the host are disabled during the time the 'AC01s are programmed. This disallows the host from receiving or sending any data to or from the 'AC01s.

The output data (DOUT) from the 'AC01 operating in the master mode is available at the falling edge of the master frame-sync signal. In the primary communication interval, this data represents the 14-bit A/D conversion result. The two least significant bits (LSBs), D01 and D00, determine whether the data is generated by the master or its slave as follows:

	D01	D00
Master mode	0	0
Slave mode	0	1

In the secondary communication interval, the data available at DOUT represents the contents of the register read with the eight MSBs set to 0 and the read/write bit set to logic 1 during the primary interval. If no register read is requested, the second word is all 0s.

The output data at DOUT from the 'AC01 operating in slave mode is available at either the falling edge of the external frame sync signal (which is the delayed frame sync from the master) or the rising edge of the external SCLK signal, whichever comes first.

When the AC01 receives an interrupt, the service routine first determines whether the received data is from the master or the slave by checking the LSBs of the received data at bit positions D01 and D00. If the LSBs are 00, the received data is stored in a memory buffer, which holds all data received from the master. The service routine also sends data from a memory buffer, which holds all data going to the master. If the LSBs of the received data are 01, data is received from and sent to the slave 'AC01, using dedicated memory buffers. This can be used with double buffering or circular buffers to allow the ISR to notify the main routine. This occurs when new input data is available for processing and/or space is available to accept processed data for output to or from the master and the slave.

### Example 3–3. Master-Slave Mode

```
*****
* This file includes the AC01 registers initialization
* All registers have 2 control bits that initiates serial communication
* There are 2 communication modes - primary and secondary communications
* During primary communication the control bits D00 and D01 are 11 to request
* for a secondary communication. In the secondary serial communications the
* control bits D15 and D14 perform same control function as primary.
* The R/W~ bit at reset is set to 0 placing the device in write mode.
* DS7-DS00 -> Number of SCLK's between FS~ and FSD~. When slaves are used,
* this should be the last register to be programmed The minimum value for this
* register should be decimal 18. This means that the time interval between the
* FS~ and FSD~ with an SCLK * frequency of 2.592 MHz (with an MCLK of 10.368 MHz)
* is 18 1/2.592 MHz = 6.94 us
; DS7-DS00 -> # of frame sync signals generated by AC01
; Therefore, number of frame sync signals number of slave = devices + 1
; In programming the AC01 REG7 is the last register to be programmed if the
; configuration is master slave mode configuration

### 3.3 Software Stack

A '54x device has a software stack whose location is determined by the contents of the stack pointer (SP). When using the software stack, you must accommodate anticipated storage requirements. The system stack fills from high to low memory addresses, as shown in Figure 3–3. The SP always points to the last element pushed onto the stack. A push performs a predecrement and a pop performs a postincrement of the system stack pointer. The stack is used during subroutine calls and returns and inside the subroutine as temporary storage.

The CALL, CALLD, CC, CCD, CALA, and CALAD instructions push the value of the program counter (PC) onto the stack. The RET and RETD instructions pop the stack and places its value into the program counter. The contents of any memory-mapped register can be pushed onto and popped from the stack, using the PSHM and POPM instructions. Two additional instructions, PSHD, and POPD, are included in the instruction set so that data memory values can be pushed onto and popped from the stack.

Figure 3–3. System Stack

### **3.4 Context Switching**

Before you execute a routine, you must save its context and restore the context after the routine has finished. This procedure is called context switching, and involves pushing the PC onto the stack. Context switching is useful for subroutine calls, especially when making extensive use of the auxiliary registers, accumulators, and other memory-mapped registers.

Due to system and CPU requirements, the order of saving and restoring can vary. Some repeat instructions, such as RPTB, are interruptible. To nest repeat block instructions, you must ensure that the block-repeat counter (BRC), block-repeat start address (RSA), and block-repeat end address (REA) registers are saved and restored.

You must also ensure that the block-repeat active flag (BRAAF) is properly set. Since the block-repeat flag can be deactivated by clearing the BRAAF bit of the ST1 register, the order in which you push the block-repeat counter and ST1 is important. If the BRC register is pushed onto the stack prior to ST1, any PC discontinuity in RPTB can give a wrong result, since BRAAF is cleared in ST1. Thus, you must restore BRC before restoring the ST1 register.

A context save complements the restored contents. To ensure the integrity of the code, determine what contents must be restored so that no sequencing is lost.

*Example 3–4. Context Save and Restore for TMS320C54x*

### 3.5 Interrupt Handling

The '54x CPU supports 16 user-maskable interrupts. The vectors for interrupts not used by a '54x device can function as software interrupts, using the INTR and TRAP instructions. TRAP and INTR allow you to execute any of the 32 available ISRs. You can define other locations in the interrupt vector table. The INTR instruction sets the INTM bit to 1, clears the corresponding interrupt flag to 0, and makes the  $\overline{\text{ACK}}$  signal active, but the TRAP instruction does not. INTR and TRAP are nonmaskable interrupts.

When a maskable interrupt occurs, the corresponding flag is set to 1 in the interrupt flag register (IFR). Interrupt processing begins if the corresponding bit in IMR register is set to 1 and the INTM bit in the ST1 register is cleared. The IFR register can be read and action taken if an interrupt occurs. This is true even when the interrupt is disabled. This is useful when not using an interrupt-driven interface, such as in a subroutine call when INT1 has not occurred.

When interrupt processing begins, the PC is pushed onto the stack and the interrupt vector is loaded into the PC. Interrupts are then disabled by setting INTM = 1. The program continues from the address loaded in the PC. Since all interrupts are disabled, the program can be processed without any interruptions, unless the ISR reenables them. Except for very simple ISRs, it is important to save the processor context during execution of the routine.

During the time the 'AC01 is reset, the DSP initializes the serial port and sets up the interrupt. To set up the interrupts, it performs the following operations:

- Enables unmasked interrupts by clearing the interrupt mode bit (INTM)
- Clears prior receive interrupts by writing the current contents of the appropriate receive interrupt flag in the IFR back to the IFR
- Enables receive interrupts by setting the appropriate receive interrupt flag in the interrupt mask register (IMR)

The initialization of the IMR and IFR registers and the INTM bit is included in the serial port and the 'AC01 initialization.

Example 3–5 processes the receive interrupt 1 service routine. The routine collects 256 samples in the first buffer and changes the address to the second buffer for the next 256 samples while processing the first buffer.

### 3.6 Interrupt Priority

Interrupt prioritization allows interrupts that occur simultaneously to be serviced in a predefined order. For instance, infrequent but lengthy ISRs can be interrupted frequently. In Example 3–6, the ISR for the INT1 bit includes context save and restore macros. When the routine has finished processing, the IMR is restored to its original state. Notice that the RETE instruction not only pops the next program counter address from the stack, but also clears the INTM bit to 0. This enables all interrupts that have their IMR bit set.

#### Example 3–6. Interrupt Service Routine (ISR)

```
.title "Interrupt Service Routine"
.mmregs
intl:
    CONTEXT_STORE          ; push the contents of accumulators and registers on stack
    STM    #K_INT0,IMR    ; Unmask only INT0~
    RSBX   INTM           ; Enable all Interrupts
;
; Main Processing for Receive Interrupt 1
.
.
.
    SSBX   INTM           ; Disable all interrupts
    CONTEXT_RESTORE      ; pop accumulators and registers
    RETE                ; return and enable interrupts
.end
```

There is a potential conflict between the INTM bit disable and context restore. If an interrupt 0 (INT0) occurs during context restore, the macro CONTEXT\_RESTORE is executed before servicing INT0. This can trigger an INT0. If INTM is cleared during the context restore, it branches to the INT0 service routine. If you reenables the interrupts when INTM returns from INT0, a conflict occurs, because INTM is set to 0 and its original contents are lost. To preserve the contents of the INTM bit, do not enable the interrupts when INTM returns from the INT0 service routine. During interrupt priorities, preserve the INTM and IMR bits for the system requirements.

### 3.7 Circular Addressing

Circular addressing is an important feature of the '54x instruction set. Algorithms for convolution, correlation, and FIR filters can use circular buffers in memory. In these algorithms, the circular buffers implement a sliding window that contains the most recent data. As new data comes in, it overwrites the oldest data. The size, the bottom address, and the top address of the circular buffer are specified by the block size register (BK) and a user-selected auxiliary register (ARn). A circular buffer size of R must start on a K-bit boundary (that is, the K LSBs of the starting address of the circular buffer must be 0), where K is the smallest integer that satisfies  $2^K > R$ .

Circular addressing can be used for different functions of an application. For example, it can be used for collecting the input samples in a block. It can also be used in processing samples in blocks and data in the output buffer. In Example 3–7, a frame of 256 samples is collected from the serial port to process the data using the circular addressing mode. The output from the processed block is sent to the D/A converter through the serial port register using circular buffers. A ping-pong buffering scheme is used. While processing the first buffer, samples are collected in the second buffer, and vice versa. The real-time operation of the system is not disturbed and no data samples are lost.

#### Example 3–7. Circular Addressing Mode

### 3.8 Buffered Serial Port

The buffered serial port (BSP) is made up of a full-duplex, double-buffered serial port interface, which functions in a similar manner to the '54x standard serial port, and an autobuffering unit (ABU). The serial port section of the BSP is an enhanced version of the '54x standard serial port. The ABU is an additional section of logic which allows the serial port section to read/write directly to '54x internal memory independent of the CPU. This results in a minimum overhead for serial port transfers and faster data rates. The full duplex BSP serial interface provides direct communication with serial devices such as codecs, serial A/D converters, and other serial devices with a minimum of external hardware. The double-buffered BSP allows transfer of a continuous communication stream in 8-,10-,12- or 16-bit data packets. This section uses the '542 device to verify the BSP functionality.

The autobuffering process occurs between the ABU and the 2K-word block of ABU memory. Each time a serial port transfer occurs, the data involved is automatically transferred to or from a buffer in the 2K-word block of memory under control of the ABU. No interrupts are generated with each word transfer in autobuffering mode. Interrupts are generated to the CPU each time one of the half-boundaries is crossed. When autobuffering capability is disabled (standard mode), transfers with the serial port are performed under user control (software). When autobuffering is enabled, word transfers can be done directly between the serial port and '54x internal memory using the ABU embedded address generators. The ABU has its own set of circular addressing registers with corresponding address generation units. The length and starting addresses of the buffers are user programmable. A buffer empty/full interrupt can be posted to the CPU.

The six MSBs in the BSP control extension register (BSPCE) configure the ABU. Bits 14 and 11 are read only and the remaining bits are read/write. Figure 3–4 shows the bit positions of BSPCE and Table 3–1 provides a summary of each bit.

Figure 3–4. BSP Control Extension Register (BSPCE) Diagram

Table 3–1. BSP Control Extension Register (BSPCE) Bit Summary

Bit	Name	Function
15	HALTR	Autobuffering Receive Halt. This control bit determines whether autobuffering receive is halted when the current half of the buffer has been received.  HALTR = 0    Autobuffering continues to operate when the current half of the buffer has been received.  HALTR = 1    Autobuffering is halted when the current half of the buffer has been received. When this occurs, the BRE bit is cleared to 0 and the serial port continues to operate in standard mode.
14	RH	Receive Buffer Half Received. This read-only bit indicates which half of the receive buffer has been filled. Reading RH when the RINT interrupt occurs (seen either as a program interrupt or by polling IFR) is a convenient way to identify which boundary has just been crossed.  RH = 0        The first half of the buffer has been filled and that receptions are currently placing data in the second half of the buffer.  RH = 1        The second half of the buffer has been filled and that receptions are currently placing data in the first half of the buffer.
13	BRE	Autobuffering Receive Enable. This control bit enables autobuffering receive.  BRE = 0        Autobuffering is disabled and the serial port interface operates in standard mode.  BRE = 1        Autobuffering is enabled for the receiver.
12	HALTX	Autobuffering Transmit Halt. This control bit determines whether autobuffering transmit is halted when the current half of the buffer has been transmitted.  HALTX = 0    Autobuffering continues to operate when the current half of the buffer has been transmitted.  HALTX = 1    Autobuffering is halted when the current half of the buffer has been transmitted. When this occurs, the BXE bit is cleared to 0 and the serial port continues to operate in standard mode.
11	XH	Transmit Buffer Half Transmitted. This read-only bit indicates which half of the transmit buffer has been transmitted. Reading XH when the XINT interrupt occurs (seen either as a program interrupt or by polling IFR) is a convenient way to identify which boundary has just been crossed.  XH = 0        The first half of the buffer has been transmitted and transmissions are currently taking data from the second half of the buffer.  XH = 1        The second half of the buffer has been transmitted and transmissions are currently taking data from the first half of the buffer.

*Table 3–1. BSP Control Extension Register (BSPCE) Bit Summary (Continued)*

Bit	Name	Function
10	BXE	Autobuffering Transmit Enable. This control bit enables the autobuffering transmit.
		BXE = 0      Autobuffering is disabled and the serial port operates in standard mode.
		BXE = 1      Autobuffering is enabled for the transmitter.
9	PCM	Pulse Code Modulation Mode. This control bit puts the serial port in pulse code modulation (PCM) mode. The PCM mode only affects the transmitter. BDXR-to-BXSR transfer is not affected by the PCM bit value.
		PCM = 0      Pulse code modulation mode is disabled.
		PCM = 1      Pulse code modulation mode is enabled. In PCM mode, BDXR is transmitted only if its most significant ( $2^{15}$ ) bit is set to 0. If this bit is set to 1, BDXR is not transmitted and BDX is put in high impedance during the transmission period.
8	FIG	Frame Ignore. This control bit operates only in transmit continuous mode with external frame and in receive continuous mode.
		FIG = 0      Frame sync pulses following the first frame pulse restart the transfer.
		FIG = 1      Frame sync pulses following the first frame pulse that initiates a transfer operation are ignored.
7	FE	Format Extension. The FE bit in conjunction with FO in the SPC register specifies the word length. When FO FE = 00, the format is 16-bit words; when FO FE = 01, the format is 10-bit words; when FO FE = 10, the format is 8-bit words; and when FO FE = 11, the format is 12-bit words. Note that for 8-, 10-, and 12-bit words, the received words are right justified and the sign bit is extended to form a 16-bit word. Words to transmit must be right justified.
6	CLKP	Clock Polarity. This control bit specifies when the data is sampled by the receiver and transmitter.
		CLKP = 0      Data is sampled by the receiver on BCLKR falling edge and sent by the transmitter on BCLKX rising edge.
		CLKP = 1      Data is sampled by the receiver on BCLKR rising edge and sent by the transmitter on BCLKX falling edge.
5	FSP	Frame Sync Polarity. This control bit specifies whether frame sync pulses (BFSX and BFSR) are active high or low.
		FSP = 0      Frame sync pulses (BFSX and BFSR) are active high.
		FSP = 1      Frame sync pulses (BFSX and BFSR) are active low.

Table 3–1. BSP Control Extension Register (BSPCE) Bit Summary (Continued)

Bit	Name	Function
4–0	CLKDV	Internal Transmit Clock Division factor. When the MCM bit of BSPC is set to 1, CLKX is driven by an on-chip source having a frequency equal to $1/(\text{CLKDV}+1)$ of CLKOUT. CLKDV range is 0–31. When CLKDV is odd or equal to 0, the CLKX duty cycle is 50%. When CLKDV is an even value ( $\text{CLKDV}=2p$ ), the CLKX high and low state durations depend on CLKP. When CLKP is 0, the high state duration is $p+1$ cycles and the low state duration is $p$ cycles; when CLKP is 1, the high state duration is $p$ cycles and the low state duration is $p+1$ cycles.

The autobuffering process for transmit is illustrated in Figure 3–5 and for receive in Figure 3–6. When a process is activated upon request from the serial port ( $\text{XRDY} = 1$  or  $\text{RRDY} = 1$ ), four actions are performed:

- 1) '54x internal memory access,
- 2) address register update,
- 3) decision for interrupt,
- 4) autodisable management.

An interrupt is generated whenever the first or second half-of-buffer is processed. The RH and XH bits in BSPCE allow you to know which half has been processed when an interrupt boundary is found. For further details on BSP operation, refer to the *TMS320C54x DSP Reference Set, Volume 1: CPU and Peripherals*.

Figure 3–5. Autobuffering Process for Transmit

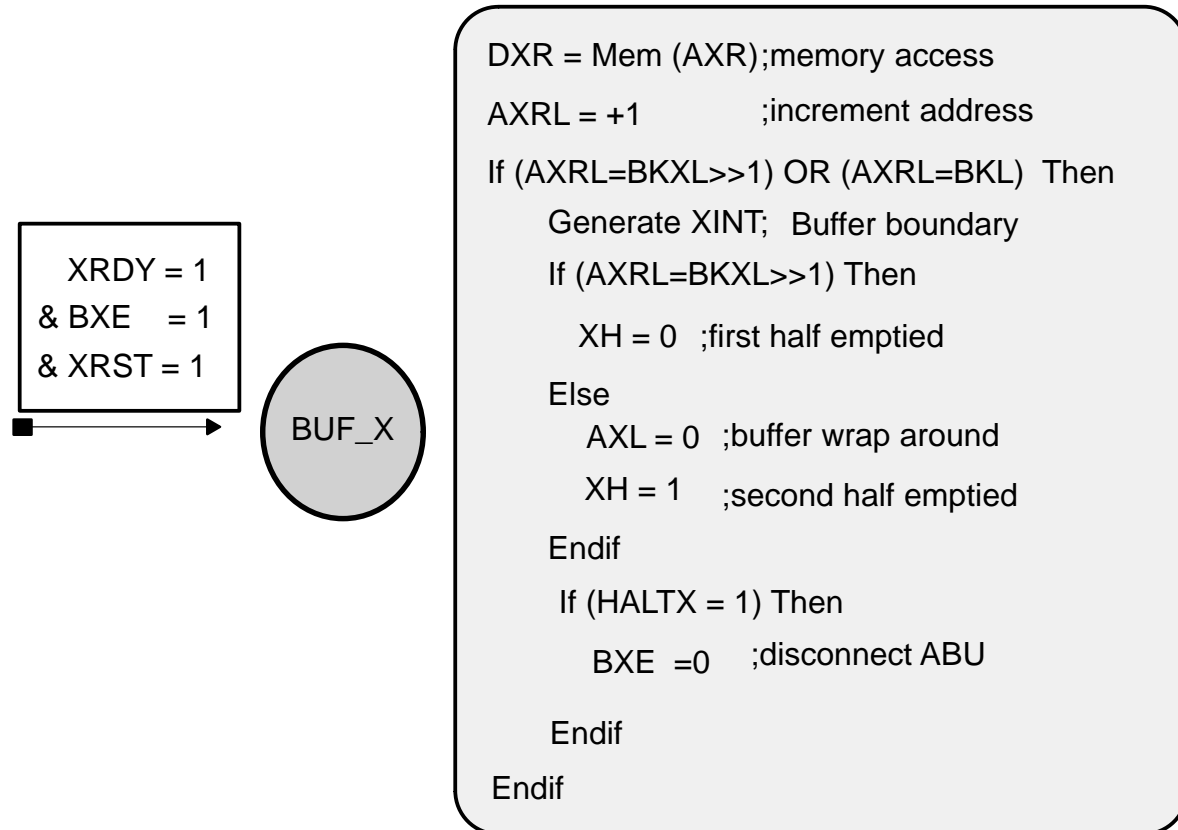

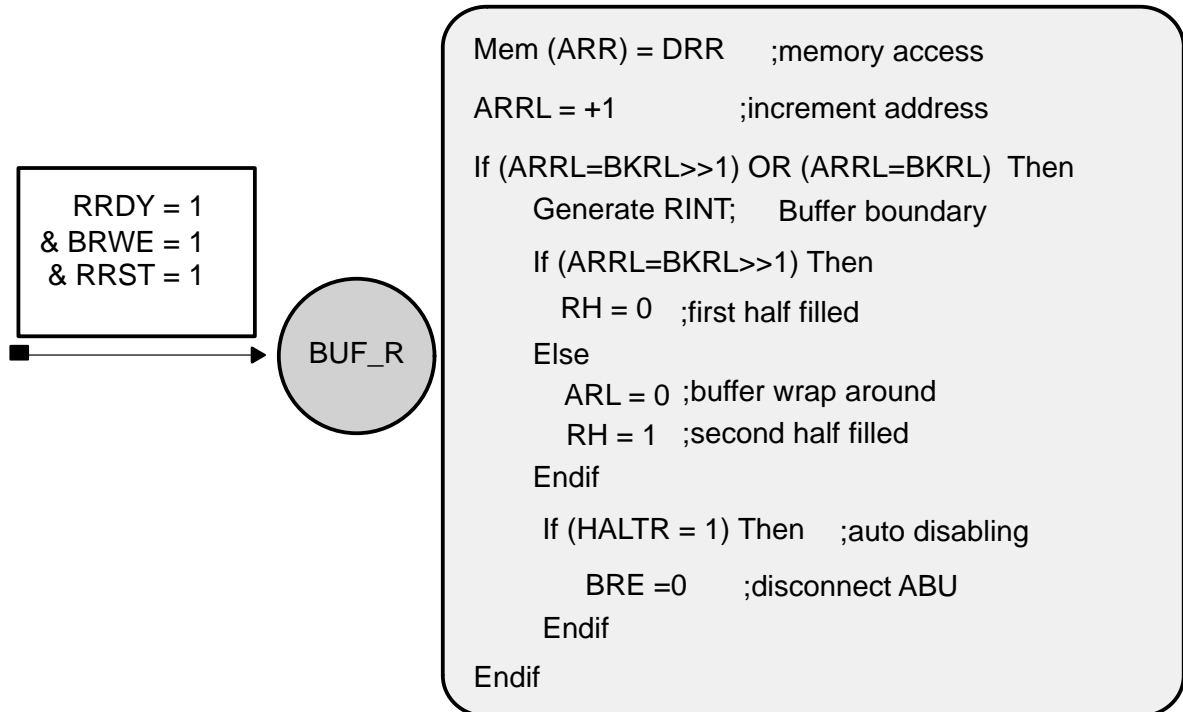

Figure 3–6. Autobuffering Process for Receive

### **Initialization Examples**

In order to start or restart BSP operation in standard mode, the same steps are performed in software as with initializing the serial port (see *TMS320C54x DSP Reference Set, Volume 1: CPU and Peripherals*), in addition to which, the BSPCE register must be initialized to configure any of the enhanced features desired. To start or restart the BSP in autobuffering mode, a similar set of steps must also be performed, in addition to which, the autobuffering registers must be initialized.

As an illustration of the proper operation of a buffered serial port, Example 3–8 and Example 3–9 define a sequence of actions. The '542 peripheral configuration has been used as a reference for these examples. The examples show the actions for initializing the BSP for autobuffering mode operation. In both cases, assume that transmit and receive interrupts are used to service the ABU interrupts.

Example 3–8 initializes the serial port for transmit operations only, with burst mode, external frame sync, and external clock selected. The selected data format is 16 bits, with frame sync and clock polarities selected to be high true. Transmit autobuffering is enabled by setting the BXE bit in the BSPCE, and HALTX has been set to 1, which causes transmission to halt when half of the defined buffer is transmitted.

Example 3–9 initializes the serial port for receive operations only. Receive autobuffering is enabled by setting the BRE and HALTR bits in the BSPCE to 1.

The complete initialization code is shown in Example 3–10 on page 3-36.

*Example 3–8. BSP Transmit Initialization Routine*

<b>Action</b>	<b>Description</b>
1) Reset and initialize the serial port by writing 0008h to SPC.	This places both the transmit and receive portions of the serial port in reset and sets up the serial port to operate with externally generated FSX and CLKX signals and FSX required for transmit/receive of each 16-bit word.
2) Clear any pending serial port interrupts by writing 0020h to IFR.	Eliminate any interrupts that may have occurred before initialization.
3) Enable the serial port interrupts by ORing 0020h with IMR.	Enable transmit interrupts.
4) Enable interrupts globally (if necessary) by clearing the INTM bit in ST1.	Interrupts must be globally enabled for the CPU to respond.
5) Initialize the ABU transmit by writing 1400h to BSPCE.	This causes the autobuffering mode to stop when the current half-of-buffer has been transmitted.
6) Write the buffer start address to AXR.	Identify the transmit buffer register address.
7) Write the buffer size to BKX.	Identify the buffer size of the ABU.
8) Start the serial port by writing 0048h to SPC.	This takes the transmit portion of the serial port out of reset and starts operations with the conditions defined in steps 1 and 5.

*Example 3–9. BSP Receive Initialization Routine*

<b>Action</b>	<b>Description</b>
1) Reset and initialize the serial port by writing 0000h to SPC.	This places both the transmit and receive portions of the serial port in reset and sets up the serial port to operate with externally generated FSR and CLKR signals and FSR required for transmit/receive of each 16-bit word.
2) Clear any pending serial port interrupts by writing 0010h to IFR.	Eliminate any interrupts that may have occurred before initialization.
3) Enable the serial port interrupts by ORing 0010h with IMR.	Enable receive interrupts.
4) Enable interrupts globally (if necessary) by clearing the INTM bit in ST1.	Interrupts must be globally enabled for the CPU to respond.
5) Initialize the ABU transmit by writing A000h to BSPCE.	This causes the autobuffering mode to stop when the current half-of-buffer has been received.
6) Write the buffer start address to ARR.	Identify the receive buffer register address.
7) Write the buffer size to BKR.	Identify the buffer size of the ABU.
8) Start the serial port by writing 0088h to SPC.	This takes the receive portion of the serial port out of reset and starts operations with the conditions defined in steps 1 and 5.

; Writes new configuration data into the AC01. Assuming a system
; which processes speech signals and * requires the following parameters
; Low pass filter cut-off frequency = 3.6 kHz
; Sampling rate = 8000 Hz
; Assume the Master clock MCLK = 10.368 MHz
; This example demonstrates how to program these parameters -
; the registers affected are:
; Register A which determines the division of the MCLK frequency
; to generate the internal filter clock FCLK.
; It also determines the -3 dB corner frequency of the low-pass filter
; Register B which determines the division of FCLK to generate
; the sampling (conversion) frequency
; It also determines the -3dB corner frequency of the high-pass filter

# Signal Processing

---

---

---

---

Certain features of the '54x architecture and instruction set facilitate the solution of numerically intensive problems. Some examples include filtering, encoding techniques in telecommunication applications, and speech recognition. This chapter discusses digital filters that use both fixed and adaptive coefficients and fast Fourier transforms.

<b>Topic</b>	<b>Page</b>
<b>4.1 Finite Impulse Response (FIR) Filters .....</b>	<b>4-2</b>
<b>4.2 Infinite Impulse Response (IIR) Filters .....</b>	<b>4-9</b>
<b>4.3 Adaptive Filtering .....</b>	<b>4-12</b>
<b>4.4 Fast Fourier Transforms (FFTs) .....</b>	<b>4-19</b>

## 4.1 Finite Impulse Response (FIR) Filters

Digital filters are a common requirement for digital signal processing systems. There are two types of digital filters: finite impulse response (FIR) and infinite impulse response (IIR). Each of these can have either fixed or adaptive coefficients.

If an FIR filter has an impulse response,  $h(0), h(1), \dots, h(N-1)$ , and  $x[n]$  represents the input of the filter at time  $n$ , the output  $y[n]$  at time  $n$  is given by the following equation:

$$y(n) = h(0)x(n) + h(1)x(n-1) + h(2)x(n-2) + \dots + h(N-1)x[n-(N-1)]$$

Figure 4–1 illustrates a method using circular addressing to implement an FIR filter. To set up circular addressing, initialize BK to block length  $N$ . The locations for `d_data_buffer`, and impulse responses, `COFF_FIR`, must start from memory locations whose addresses are multiples of the smallest power of 2 that is greater than  $N$ . For instance, if  $N = 11$ , the first address for `d_data_buffer` must be a multiple of 16. Thus, the lowest four bits of the beginning address must be 0.

Figure 4–1. Data Memory Organization in an FIR Filter

In Example 4–1,  $N$  is 16 and the circular buffer starts at an address whose four LSBs are 0.

```

In a second method, two features of the '54x device facilitate implementation of the FIR filters: circular addressing and the FIRS instruction. The FIR filter shown in Figure 4–2, with symmetric impulse response about the center tap, is widely used in digital signal processing applications because of its linear phase response. In applications such as speech processing, linear phase response is required to avoid phase distortion, which degrades the quality of the signal waveforms. The output of the filter for length N is given by:

$$y(n) = \sum_{k=0}^{N/2-1} h(k)[x(n-k) + x(n-(N-1+k))] \quad n = 0, 1, 2$$

*Figure 4–2. Block Diagram of an Nth-Order Symmetric FIR Filter*

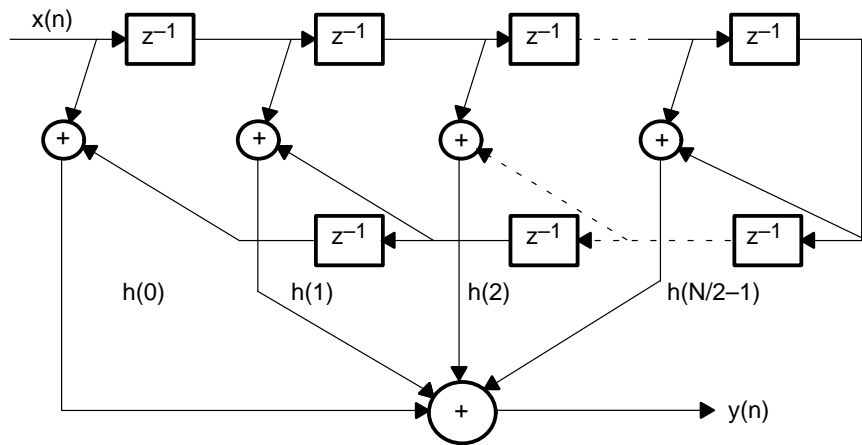

Figure 4–3 shows the storage diagram of the input sequence for two circular buffers. To build the buffers, the value of  $N/2$  is loaded into a circular buffer size register. AR4 is set to point to the top of buffer 1 and AR5 points to the bottom of buffer 2. The data at the top of buffer 1 is moved to the bottom of buffer 2 for the delayed operation before storing new sample data in buffer 1. The processor then performs the adds and multiplies  $h(0)\{x(0)+x(-N+1)\}$ . After each iteration of the filtering routine, AR4 points to the next time slot window for the data move and AR5 points to the next input sample. For the next iteration of the filtering routine, AR4 points to address 1 and AR5 points to address  $N/2-2$ .

Figure 4–3. Input Sequence Storage

Example 4–2 shows how to implement a symmetric FIR filter on the '54x. It uses the symmetrical finite impulse response (FIRS) instruction and the repeat next instruction and clear accumulator (RPTZ) instruction together. FIRS can add two data values (input sequences stored in data memory) in parallel with multiplication of the previous addition result using an impulse response stored in program memory. FIRS becomes a single-cycle instruction when used with the single-repeat instruction. To perform the delayed operation in this storage scheme, two circular buffers are used for the input sequence.

*Example 4–2. Symmetric FIR Implementation Using FIRS Instruction*

### 4.2 Infinite Impulse Response (IIR) Filters

IIR filters are widely used in digital signal processing applications. The transfer function of an IIR filter is given by:

$$H(z) = \frac{b_0 + b_1z^{-1} + \dots + b_Mz^{-M}}{1 + a_1z^{-1} + \dots + a_Nz^{-N}} = \frac{Y(z)}{X(z)}$$

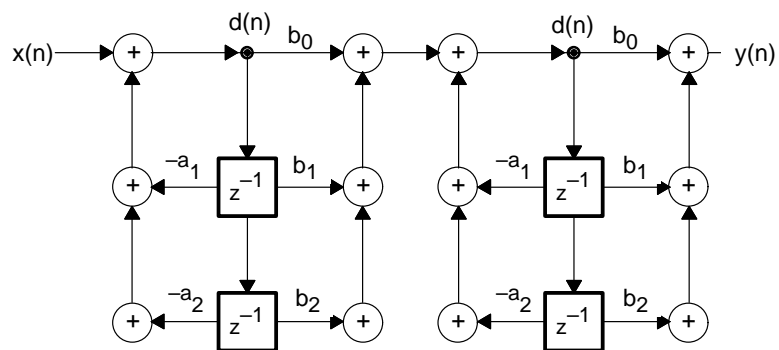

The transfer function has both poles and zeros. Its output depends on both input and past output. IIR filters need less computation than FIR filters. However, IIR filters have stability problems. The coefficients are very sensitive to coefficient quantization. Figure 4–4 shows a typical diagram of an IIR filter.

Figure 4–4. Nth-Order Direct-Form Type II IIR Filter

Most often, IIR filters are implemented as a cascade of second-order sections, called biquads. The block diagram is shown in Figure 4–5.

### 4.3 Adaptive Filtering

Some applications for adaptive FIR and IIR filtering include echo and acoustic noise cancellation. In these applications, an adaptive filter tracks changing conditions in the environment. Although in theory, both FIR and IIR structures can be used as adaptive filters, stability problems and the local optimum points of IIR filters makes them less attractive for this use. FIR filters are used for all practical applications. The LMS, STMPY, and RPTBD instructions on the '54x can reduce the execution time of code for adaptive filtering. The block diagram of an adaptive FIR filter is shown in Figure 4-6. The Adaptive filtering routine is shown in Example 4-4, page 4-14.

Figure 4-6. Adaptive FIR Filter Implemented Using the Least-Mean-Squares (LMS) Algorithm

On the '54x, one coefficient can be adapted by using the least-mean-squares (LMS) algorithm, which is given by

$$b_k(i+1) = b_k(i) + 2\beta e(i)x(i-k),$$

where:

$$e(i) = d(i) - y(i)$$

The output of the adaptive filter is given by

$$y(i) = \sum_{k=0}^{N-1} b_k x(i-k)$$

The LMS instruction can perform a MAC instruction and an addition with rounding in parallel. The LMS algorithm calculates the filter output and updates each coefficient in the filter in parallel by using the LMS instruction, along with the ST||MPY and RPTBD instructions. For each coefficient in the filter at a given instant,  $2\beta e(i)$  is a constant. This factor can be computed once and stored in the temporary register, T, to use in each of the updates. The ST||MPY instruction multiplies a data sample by this factor, then the LMS instruction updates a coefficient in the filter and accumulates the filtered output. Since the factor is stored in T, the adaptive filtering in a time-slot window is performed in N cycles.

An adaptive filter can be used in modeling to imitate the behavior of a physical dynamic system. Figure 4–7 shows a block diagram of system identification, where the adaptive filter adjusts itself to cause its output to match that of the unknown system.  $H(z)$  is the impulse response of an unknown system; for example, the echo response in the case of an acoustic echo cancellation system. The signal  $x(n)$  trains the system. The size of the adaptive filter is chosen to be N, where N is the number of taps (coefficients) of the known system,  $W(z)$ .

Two circular buffers store the input sequence. AR3 points to the first buffer, AR2 points to the coefficients of  $H(z)$ , AR4 points to the coefficients of  $W(z)$ , and AR5 points to the second buffer. The newest sample is stored in a memory location that is input to the adaptive filter. The input sample is subtracted from the output of the adaptive filter to obtain the error data for the LMS algorithm. In this example, the adaptive filter output is computed for the newest sample and the filter coefficients are updated using the previous sample. Thus, there is an inherent delay between the update of the coefficient and the output of the adaptive filter.

## 4.4 Fast Fourier Transforms (FFTs)

FFTs are an efficient class of algorithms for the digital computation of the  $N$ -point discrete Fourier transform (DFT). In general, their input sequences are assumed to be complex. When input is purely real, their symmetric properties compute the DFT very efficiently.

One such optimized real FFT algorithm is the packing algorithm. The original  $2N$ -point real input sequence is packed into an  $N$ -point complex sequence. Next, an  $N$ -point FFT is performed on the complex sequence. Finally the resulting  $N$ -point complex output is unpacked into the  $2N$ -point complex sequence, which corresponds to the DFT of the original  $2N$ -point real input.

Using this strategy, the FFT size can be reduced by half, at the FFT cost function of  $O(N)$  operations to pack the input and unpack the output. Thus, the real FFT algorithm computes the DFT of a real input sequence almost twice as fast as the general FFT algorithm. The following subsections show how to perform a 16-point real FFT ( $2N = 16$ ).

### 4.4.1 Memory Allocation for Real FFT Example

The memory organization for the real FFT example in Chapter 10, *Application Code Examples*, uses the memory configuration shown in Figure 4–8 on page 4-20.

The following tables give the organization of values in data memory from the beginning of the real FFT algorithm to its end. Initially, the original  $2N$ -point real input sequence,  $a(n)$ , is stored in the lower half of the  $4N$ -word data processing buffer, as shown in Figure 4–9 on page 4-21.

## 4.4.2 Real FFT Example

The '54x real FFT algorithm is a radix-2, in-place DFT algorithm. It is shown in the following subsections in four phases :

- 1) Packing and bit-reversal of input
- 2) N-point complex FFT
- 3) Separation of odd and even parts
- 4) Generation of final output

Initially, any real input sequences of 16 to 1024 points can be used by simply modifying the constants `K_FFT_SIZE` and `K_LOGN` appropriately, defined in file `main.inc`. (The real input size is described as  $2N$  and the FFT size in phase two as  $N$ .) For a 256-point real input, for example, `K_FFT_SIZE` must be set to 128, not 256, and `K_LOGN` must be 7, not 8. Input data is assumed to be in Q15 format.

### 4.4.2.1 Phase 1: Packing and Bit-Reversal of Input

In phase 1, the input is bit-reversed so that the output at the end of the entire algorithm is in natural order. First, the original  $2N$ -point real input sequence is copied into contiguous sections of memory labeled `real_fft_input` and interpreted as an  $N$ -point complex sequence,  $d[n]$ . The even-indexed real inputs form the real part of  $d[n]$  and the odd-indexed real inputs form the imaginary part. This process is called packing. ( $n$  is a variable indicating time and can vary from 0 to infinity, while  $N$  is a constant). Next, this complex sequence is bit-reversed and stored into the data processing buffer, labeled `fft_data`.

- 1) Arrange the real input sequence,  $a(n)$  for  $n = 0, 1, 2, \dots, n - 1$ , as shown in Figure 4–9. Divide  $a(n)$  into two sequences as shown in Figure 4–10. The first is the original input sequence from `0C10h` to `0C1Fh`. The other is a packed sequence:

for  $n = 0, 1, 2, \dots, N - 1$

- 2) Form the complex FFT input,  $d(n)$ , by using  $r(n)$  for the real part and  $i(n)$  for the imaginary part:

$$d(n) = r(n) + j i(n)$$

- 3) Store  $d(n)$  in the upper half of the data processing buffer in bit-reversed order as shown in Figure 4–10 on page 4-23.

Figure 4–10. Phase 1 Data Memory

0C00h	r(0) = a(0)
0C01h	i(0) = a(1)

0C1Ch	a(12)
0C1Dh	a(13)
0C1Eh	a(14)
0C1Fh	a(15)

**4.4.2.2 Phase 2: N-Point Complex FFT**

In phase 2, an N-point complex FFT is performed in place in the data-processing buffer. The twiddle factors are in Q15 format and are stored in two separate tables, pointed to by sine and cosine. Each table contains 512 values, corresponding to angles ranging from 0 to almost 180 degrees. The indexing scheme used in this algorithm permits the same twiddle tables for inputs of different sizes. Since circular addressing indexes the tables, the starting address of each table must line up to an address with 0s in the eight LSBs.

- 1) Perform an N-point complex FFT on  $d(n)$ . The resulting sequence is

$$D[k] = F\{d(n)\} = R[k] + j I[k]$$

where  $R[k]$  and  $I[k]$  are the real and imaginary parts of  $D[k]$ , respectively.

- 2) Since the FFT computation is done in place, the resulting sequence,  $D[k]$ , occupies the upper half of the data-processing buffer, as shown. The lower half of the data processing buffer still contains the original real input sequence,  $a(n)$ . This is overwritten in phase 3.
- 3) All the information from the original  $2N$ -point real sequence,  $a(n)$ , is contained in this  $N$ -point complex sequence,  $D[k]$ . The remainder of the algorithm unpacks  $D[k]$  into the final  $2N$ -point complex sequence,  $A[k] = F\{a(n)\}$ .

**4.4.2.3 Phase 3: Separation of Odd and Even Parts**

Phase 3 separates the FFT output to compute four independent sequences: RP, RM, IP, and IM, which are the even real, odd real, even imaginary, and the odd imaginary parts, respectively.

- 1)  $D[k]$  is separated into its real even part,  $RP[k]$ , real odd part,  $RM[k]$ , imaginary even part,  $IP[k]$ , and imaginary odd part,  $IM[k]$ , according to the following equations:

$$RP[k] = RP[N-k] = 0.5 * (R[k] + R[N-k])$$

$$RM[k] = -RM[N-k] = 0.5 * (R[k] - R[N-k])$$

$$IP[k] = IP[N-k] = 0.5 * (I[k] + I[N-k])$$

$$IM[k] = -IM[N-k] = 0.5 * (I[k] - I[N-k])$$

$$RP[0] = R[0]$$

$$IP[0] = I[0]$$

$$RM[0] = IM[0] = RM[N/2] = IM[N/2] = 0$$

$$RP[N/2] = R[N/2]$$

$$IP[N/2] = I[N/2]$$

- 2) The table below shows the organization of the values at the end of phase three. The sequences  $RP[k]$  and  $IP[k]$  are stored in the upper half of the data processing buffer in ascending order; the sequences  $RM[k]$  and  $IM[k]$  are stored in the lower half in descending order.

0C1Bh	RM[3]
0C1Ch	IM[2]
0C1Dh	RM[2]
0C1Eh	IM[1]
0C1Fh	RM[1]

**4.4.2.4 Phase 4: Generation of Final Output**

Phase 4 performs one more set of butterflies to generate the  $2N$ -point complex output, which corresponds to the DFT of the original  $2N$ -point real input sequence. The output resides in the data processing buffer.

- 1) The four sequences,  $RP[k]$ ,  $RM[k]$ ,  $IP[k]$ , and  $IM[k]$ , are used to compute the real FFT of  $a(n)$  according to the following equations.

$$AR[k] = AR[2N - k] = RP[k] + \cos(k \pi / N) * IP[k] - \sin(k \pi / N) * RM[k]$$

$$AI[k] = -AI[2N - k] = IM[k] - \cos(k \pi / N) * RM[k] - \sin(k \pi / N) * IP[k]$$

$$AR[0] = RP[0] + IP[0]$$

$$AI[0] = IM[0] - RM[0]$$

$$AR[N] = R[0] - I[0]$$

$$AI[N] = 0$$

where:

$$A[k] = A[2N - k] = AR[k] + j AI[k] = F\{a(n)\}$$

- 2) The real FFT outputs fill up the entire  $4N$ -word data processing buffer. These outputs are real/imaginary, interleaved, and in natural order, as shown in Figure 4-13 on page 4-29. The values  $RM[0]$  and  $IM[0]$  are not stored because they are not used to compute the final outputs in phase 4.

# Resource Management

---

---

---

This chapter introduces features of the '54x that improve system performance. These features allow you to conserve power and manage memory. You can improve the performance of any application through efficient memory management. Some issues include:

- On-chip memory versus off-chip memory
- Random access variables that use direct memory addressing versus aggregate variables that include structures/arrays
- The use of pointers for accessing the arrays and pointers
- Alignment of long words to even addresses
- The K-boundary requirement for circular buffers
- Allocation of stack

This chapter also discusses unique features of the '548 and 'LC548 that help when an application needs a large amount of memory.

Topic	Page
5.1 Memory Allocation .....	5-2
5.2 Overlay Management .....	5-5
5.3 Memory-to-Memory Moves .....	5-6
5.4 Power Management .....	5-8

## 5.1 Memory Allocation

The '54x can access a large amount of program and data memory (64K words each), but can handle only a limited amount of on-chip memory. On-chip memory accesses reduce the cycle time, since there are eight different internal buses on the '54x but there is only one external bus for off-chip accesses. This means that off-chip operation requires more cycles to perform an operation than on-chip operation.

The DSP uses wait-state generators to interface to slower memories. The system, then, cannot run at full speed. If on-chip memory consists of dual access RAM (DARAM), accessing two operands from the same block does not incur a penalty. Using single access RAM (SARAM), however, incurs a cycle penalty. You can use on-chip ROM for tables to make efficient use of memory.

Random-access variables use direct addressing mode. This allocates all the random variables on a single data page, using one data page initialization for the application. Data-page relative memory addressing makes efficient use of memory resources. Each data variable has an associated lifetime. When that lifecycle is over, the data variable ceases to exist. Thus, if two data variables have non-overlapping lifetimes, both can occupy the same physical memory. All random variables, then, can form unions in the linker command file.

The actual lifetime of a variable determines whether it is retained across the application or only in the function. By careful organization of the code memory, resources can be used optimally. Aggregate variables, such as arrays and structures, are accessed via pointers located within that program's data page. Aggregate variables reside elsewhere in memory. Depending upon the lifetime of the arrays or structures, these can also form unions accordingly.

Memory management is required for interrupt-driven tasks. Often, programmers assume that all CPU resources are available when required. This may not be the case if tasks are interrupted periodically. These interrupts do not require many CPU resources, but they force the system to respond within a certain time. To ensure that interrupts occur within the specified time and the interrupted code resumes as soon as possible, you must use low overhead interrupts. If the application requires frequent interrupts, you can use some of the CPU resources for these interrupts. For example, when all CPU resources are used, simply saving and restoring the CPU's contents increases the overhead for an interrupt service routine (ISR).

A dedicated auxiliary register is useful for servicing interrupts. Allowing interrupts at certain places in the code permits the various tasks of an application to reuse memory. If the code is fully interruptible (that is, interrupts can occur anywhere and interrupt response time is assured within a certain period),

memory blocks must be kept separate from each other. On the other hand, if a context switch occurs at the completion of a function rather than in the middle of execution, the variables can be overlapped for efficiency. This allows variables to use the same memory addresses at different times.

Long words must be aligned at even boundaries for double-precision operations; that is, the most significant word at an even address and the least significant word at an odd address. Circular buffers start at a  $K$  boundary, where  $K$  is the smallest integer that satisfies  $2^K > R$  and  $R$  is the size of the circular buffer. If an application uses circular buffers of different sizes, you must use the align directive to align the buffers to correct sizes. You can do this by allocating the largest buffer size as the first alignment, the next highest as the second alignment, and so forth. Example 5–1 shows the memory management alignment feature where the largest circular buffer is 1024 words, and therefore, is assigned first. A 256-word buffer is assigned next. Unused memory can be used for other functions without conflict.

#### Example 5–1. Memory Management

```

DRAM      : origin = 0x0100, length = 0x1300
inpt_buf  : {} > DRAM,align(1024)PAGE 1
outdata   : {} > DRAM,align(1024)PAGE 1
UNION     : > DRAM align(1024) PAGE 1
{
    fft_bfrr
    adpt_sct:
    {
        *(bufferw)
        .+=80h;
        *(bufferp)
    }
}
UNION     : > DRAM align(256) PAGE 1
{
    fir_bfrr
    cir_bfrr
    coff_iir
    bufferh
    twid_sin
}
UNION     : > DRAM align(256) PAGE 1
{
    fir_coff
    cir_bfrr
    bufferx
    twid_cos
}

```

Stack allocation can also benefit from efficient memory management. The stack grows from high to low memory addresses. The stack pointer (SP) decrements the stack by 1 before pushing its contents, which must be preserved, onto the stack and post increments after a pop. The bottom location is added to the stack, giving the actual stack size. The last element is always empty. Whether the stack is on chip or off chip affects the cycle count for accessing data.

Example 5–2 shows stack initialization when the application is written in assembly. The variable SYSTEM\_STACK holds the size of the stack. It is loaded into the SP, which points to the end of the stack. The predecrement during the push operation and the postincrement during the pop cannot overflow the stack. Example 5–3 shows stack initialization when the application is written in C.

#### Example 5–2. Stack Initialization for Assembly Applications

```

K_STACK_SIZE      .set      100
STACK             .usect    "stack", K_STACK_SIZE
SYSTEM_STACK      .set      STACK+K_STACK_SIZE
                  .ref      SYSTEM_STACK
                  STM       #SYSTEM_STACK, SP      ; initialization
                                                         ; of SP- this is done
                                                         ; vectors.asm
stack : {} DRAM    PAGE 1      ; initialization of stack
                                                         ; in linker command file

```

The compiler uses a stack to allocate local variables, pass arguments, and save the processor status. The stack size is set by the linker and the default size is 1 K words. In Example 5–3, the .stack section creates a stack size of 1 K words. A section of 100 words is created, referenced as top\_stck and btm\_stck, for the CPU requirements. The rest of the stack (1024 – 100) words can be used for passing arguments and local variables. Only the btm\_stck is referenced in the code; hence, several sections can be created within the 1 K words of the stack.

#### Example 5–3. Stack Initialization for C Applications

```

.ref    btm_stck      ; bottom of stack label
STM     #btm_stck, SP ; initialization of SP - this is done
                                                         ; vectors.asm

.stack :
{
top_stck =.;          /* top of stack */
.+=100;              /* size of the stack */
btm_stck =.;         /* this is done in linker command
}                    file */

```

## 5.2 Overlay Management

Some systems use a memory configuration in which all or part of the memory space is overlaid. This allows the system to map different banks of physical memory into and out of a single address range. Multiple banks of physical memory can overlay each other at one address range. This is achieved by setting the OVLY bit in the PMST register. This is particularly useful in loading the coefficients of a filter, since program and data use the same physical memory.

If an application needs more than 64K words of either data or program memory, two options are available. The first extends the 16-bit address line to a 16 + n-address line for the extended memory space. The '548 provides 16 + 7 address lines to access 8M words of program space. The other option uses an external device that provides upper addresses beyond the 16-bit memory range. The DSP writes a value to a register located in its I/O space, whose data lines are the higher address bits. It implements bank switching to cross the 64K boundary. Since the bank switch requires action from the DSP, frequent switching between the banks is not very efficient. It is more efficient to partition tasks within a bank and switch banks only when starting new tasks.

The 'LC548 is designed to support a much larger program space of 8M words. Its memory-mapped register controls paging, and its extra instructions address extended program space. The OVLY bit configures the 8M words for on- or off-chip memory. If OVLY = 1, the lower half (128 pages) is a shared, on-chip, 32K-word block and the remaining 4M words are off-chip. If OVLY = 0, the entire 8M words of memory are off chip.

### 5.3 Memory-to-Memory Moves

There are various reasons for performing memory-to-memory moves. These reasons include making copies of buffers to preserve the original, moving contents from ROM to RAM, and moving copies of code from their load location to their execution location. Example 5–4 implements memory-to-memory moves on the '54x using single-instruction repeat loops.

#### *Example 5–4. Memory-to-Memory Block Moves Using the RPT Instruction*

```

;
;       .mmregs
;       .text
;
; ~~~~~~
; This routine uses the MVDD instruction to move
; information in data memory to other data memory
; locations.
; ~~~~~~
;
MOVE_DD:
    STM    #4000h,AR2    ;Load pointer to source in
                        ;data memory.
    STM    #100h,AR3     ;Load pointer to
                        ;destination in data memory.
    RPT    #(1024-1)    ;Move 1024 value.
    MVDD   *AR2+,*AR3+
    RET
;
; ~~~~~~
; This routine uses the MVDP instruction to move external
; data memory to internal program memory.
; ~~~~~~
;
MOVE_DP:
    STM    #0E000h,AR1   ;Load pointer to source in
                        ;data memory.
    RPT    #(8192-1)    ;Move 8K to program memory space.
    MVDP   *AR1+,#800h
    RET

```

## 5.4 Power Management

The '54x family of DSPs exhibits very low power dissipation and flexible power management. This is important in developing applications for portable systems, particularly wireless systems. Three aspects of power management are discussed here: on- versus off-chip memory, the use of  $\overline{\text{HOLD}}$ , and the use of IDLE modes.

To fetch and execute instructions from on-chip memory requires less power than accessing them from off-chip memory. The difference between these two accesses becomes noteworthy if a large piece of code resides off chip and is used more frequently than the on-chip code. The code can be partitioned so that the code that consumes the most power and is used most frequently is placed on-chip. (Masked ROM devices are another alternative for very high-performance applications.)

If the program is executed from internal memory and no external access occurs, switching of address outputs can be disabled with the AVIS bit in the PMST register. This feature saves a significant amount of power. However, once the AVIS bit is set, the address bus is still driven in its previous state. The external bus function in the bank-switching control register (BSCR) contributes to the state of the address, control, and data lines. If it is disabled, the address and data buses, along with the control lines, become inactive after the current bus cycle.

The  $\overline{\text{HOLD}}$  signal and the HM bit initiate a power-down mode by either shutting off CPU execution or continuing internal CPU execution if external access is not necessary. This makes external memory available for other processors. The timers and serial ports are not used, and the device can be interrupted and serviced.

Using the IDLE1, IDLE2, and IDLE3 modes dissipates less power than normal operation. The system clock is not halted in IDLE1, but CPU activities are stopped. Peripherals and timers can bring the device out of power-down mode. The system can use the timer interrupt as a wake-up if the device needs to be in power-down mode periodically. The IDLE2 instruction halts both CPU and peripherals. Unlike the IDLE1 mode, an external interrupt wakes up the processor in IDLE2. The IDLE2 mode saves a significant amount of power, compared to IDLE1. The IDLE3 mode shuts off the internal clock, also saving power.

# Arithmetic and Logical Operations

---

---

---

---

This chapter shows how the '54x supports typical arithmetic and logical operations, including multiplication, addition, division, square roots, and extended-precision operations.

Topic	Page
6.1 Division and Modulus Algorithm .....	6-2
6.2 Sines and Cosines .....	6-9
6.3 Square Roots .....	6-14
6.4 Extended-Precision Arithmetic .....	6-17
6.5 Floating-Point Arithmetic .....	6-24
6.6 Logical Operations .....	6-43

## 6.1 Division and Modulus Algorithm

The '54x implements division operations by using repeated conditional subtraction. Example 6–1 uses four types of integer division and modulus:

Type I: 32-bit by 16-bit unsigned integer division and modulus

Type II: 32-bit by 16-bit signed integer division and modulus

Type III: 16-bit by 16-bit unsigned integer division and modulus

Type IV: 16-bit by 16-bit signed integer division and modulus

SUBC performs binary division like long division. For 16-bit by 16-bit integer division, the dividend is stored in low part accumulator A. The program repeats the SUBC command 16 times to produce a 16-bit quotient in low part accumulator A and a 16-bit remainder in high part accumulator B. For each SUBC subtraction that results in a negative answer, you must left-shift the accumulator by 1 bit. This corresponds to putting a 0 in the quotient when the divisor does not go into the dividend. For each subtraction that produces a positive answer, you must left shift the difference in the ALU output by 1 bit, add 1, and store the result in accumulator A. This corresponds to putting a 1 in the quotient when the divisor goes into the dividend.

Similarly, 32-bit by 16-bit integer division is implemented using two stages of 16-bit by 16-bit integer division. The first stage takes the upper 16 bits of the 32-bit dividend and the 16-bit divisor as inputs. The resulting quotient becomes the higher 16 bits of the final quotient. The remainder is left shifted by 16 bits and adds the lower 16 bits of the original dividend. This sum and the 16-bit divisor become inputs to the second stage. The lower 16 bits of the resulting quotient is the final quotient and the resulting remainder is the final remainder.

Both the dividend and divisor must be positive when using SUBC. The division algorithm computes the quotient as follows:

- 1) The algorithm determines the sign of the quotient and stores this in accumulator B.
- 2) The program determines the quotient of the absolute value of the numerator and the denominator, using repeated SUBC commands.
- 3) The program takes the negative of the result of step 2, if appropriate, according to the value in accumulator B.

For unsigned division and modulus (types I and III), you must disable the sign extension mode (SXM = 0). For signed division and modulus (types II and IV), turn on sign extension mode (SXM = 1). The absolute value of the numerator must be greater than the absolute value of the denominator.

### Example 6–1. Unsigned/Signed Integer Division Examples

## 6.2 Sines and Cosines

Sine-wave generators are used in signal processing systems, such as communications, instrumentation, and control. In general, there are two methods to generate sine and cosine waves. The first is the table look-up method, which is used for applications not requiring extreme accuracy. This method uses large tables for precision and accuracy and requires more memory. The second method is the Taylor series expansion, which is more efficient. This method determines the sine and cosine of an angle more accurately and uses less memory than table look-up, and it is discussed here.

The first four terms of the expansion compute the angle. The Taylor series expansions for the sine and cosine of an angle are:

$$\begin{aligned}
 \sin(\theta) &= x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \frac{x^9}{9!} \\
 &= x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} \left(1 - \frac{x^2}{8.9}\right) \\
 &= x - \frac{x^3}{3!} + \frac{x^5}{5!} \left(1 - \frac{x^2}{6.7} \left(1 - \frac{x^2}{8.9}\right)\right) \\
 &= x - \frac{x^3}{3!} \left(1 - \frac{x^2}{4.5} \left(1 - \frac{x^2}{6.7} \left(1 - \frac{x^2}{8.9}\right)\right)\right) \\
 &= x \left(1 - \frac{x^2}{2.3} \left(1 - \frac{x^2}{4.5} \left(1 - \frac{x^2}{6.7} \left(1 - \frac{x^2}{8.9}\right)\right)\right)\right)
 \end{aligned}$$

$$\begin{aligned}
 \cos(\theta) &= 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \frac{x^8}{8!} \\
 &= 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} \left(1 - \frac{x^2}{7.8}\right) \\
 &= 1 - \frac{x^2}{2!} + \frac{x^4}{4!} \left(1 - \frac{x^2}{5.6} \left(1 - \frac{x^2}{7.8}\right)\right) \\
 &= 1 - \frac{x^2}{2} \left(1 - \frac{x^2}{3.4} \left(1 - \frac{x^2}{5.6} \left(1 - \frac{x^2}{7.8}\right)\right)\right)
 \end{aligned}$$

The following recursive formulas generate the sine and cosine waves:

$$\begin{aligned}
 \sin n\theta &= 2 \cos(\theta) \sin\{(n-1)\theta\} - \sin\{(n-2)\theta\} \\
 \cos n\theta &= 2 \cos(\theta) \cos\{(n-1)\theta\} - \cos\{(n-2)\theta\}
 \end{aligned}$$

These equations use two steps to generate a sine or cosine wave. The first evaluates  $\cos(\theta)$  and the second generates the signal itself, using one multiply and one subtract for a repeat counter,  $n$ .

Example 6–2 and Example 6–3 assumes that the delayed  $\cos((n-1))$  and  $\cos((n-2))$  are precalculated and are stored in memory. The Taylor series expansion to evaluate the delayed  $\cos((n-1))$ ,  $\cos((n-2))/\sin((n-1))$ , and  $\sin((n-2))$  values for a given  $\theta$  can also be used.

### 6.3 Square Roots

Example 6–4 uses a 6-term Taylor series expansion to approximate the square root of a single-precision 32-bit number. A normalized, 32-bit, left-justified number is passed to the square root function. The output is stored in the upper half of the accumulator, and the EXP and NORM instructions normalize the input value. The EXP instruction computes an exponent value in a single cycle and stores the result in T, allowing the NORM instruction to normalize the number in a single cycle. If the exponent is an odd power, the mantissa is (multiplied by 1 divided by the square root of 2) to compensate after finding the square root of the 32-bit number. The exponent value is negated to denormalize the number.

$$y^{0.5} = (1 + x)^{0.5}$$

where :

$$\begin{aligned} x &= y-1 \\ &= 1 + \frac{x}{2} - \frac{x^2}{8} + \frac{x^3}{16} - \frac{5x^4}{128} + \frac{7x^5}{256} \\ &= 1 + \frac{x}{2} - 0.5\left(\frac{x}{2}\right)^2 + 0.5\left(\frac{x}{2}\right)^3 - 0.625\left(\frac{x}{2}\right)^4 + 0.875\left(\frac{x}{2}\right)^5 \end{aligned}$$

where :

$$0.5 \leq x < 1$$

#### Example 6–4. Square Root Computation

```
*****
* Six term Taylor Series is used here to compute the square root of a number
* y^0.5 = (1+x)^0.5 where x = y-1
* = 1+(x/2)-0.5*((x/2)^2+0.5*((x/2)^3-0.625*((x/2)^4+0.875*((x/2)^5)
* 0.5 <= x < 1

## 6.4 Extended-Precision Arithmetic

Numerical analysis, floating-point computations, and other operations may require arithmetic operations with more than 32 bits of precision. Since the '54x devices are 16/32-bit fixed-point processors, software is required for arithmetic operations with extended precision. These arithmetic functions are performed in parts, similar to the way in which longhand arithmetic is done.

The '54x has several features that help make extended-precision calculations more efficient. One of the features is the carry bit, which is affected by most arithmetic ALU instructions, as well as the rotate and shift operations. The carry bit can also be explicitly modified by loading ST0 and by instructions that set or reset status register bits. For proper operation, the overflow mode bit should be reset ( $OVM = 0$ ) to prevent the accumulator from being loaded with a saturation value.

The two '54x internal data buses, CB and DB, allow some instructions to handle 32-bit operands in a single cycle. The long-word load and double-precision add/subtract instructions use 32-bit operands and can efficiently implement multi-precision arithmetic operations.

The hardware multiplier can multiply signed/unsigned numbers, as well as multiply two signed numbers and two unsigned numbers. This makes 32-bit multiplication efficient.

### 6.4.1 Addition and Subtraction

The carry bit, C, is set in ST0 if a carry is generated when an accumulator value is added to:

- The other accumulator
- A data-memory operand
- An immediate operand

A carry can also be generated when two data-memory operands are added or when a data-memory operand is added to an immediate operand. If a carry is not generated, the carry bit is cleared.

The ADD instruction with a 16-bit shift is an exception because it only sets the carry bit. This allows the ALU to generate the appropriate carry when adding to the lower or upper half of the accumulator causes a carry.

Figure 6–1 shows several 32-bit additions and their effect on the carry bit.

Figure 6–1. 32-Bit Addition

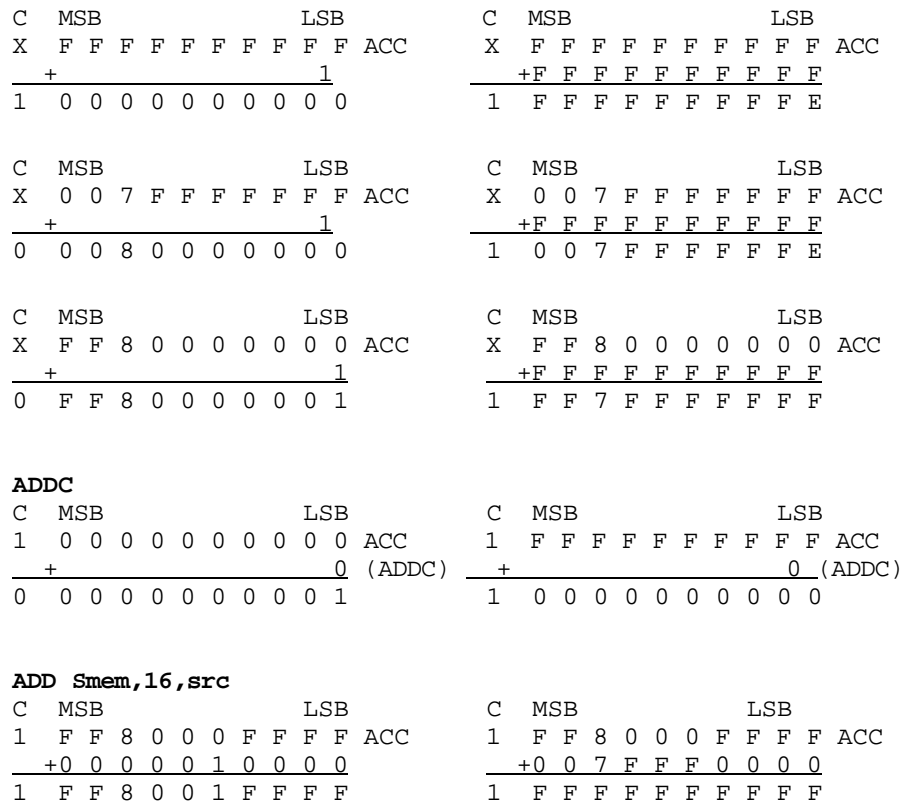

Figure 6–2. 32-Bit Subtraction

Example 6–6 subtracts two 64-bit numbers on the '54x. The partial remainder of the 64-bit subtraction is efficiently performed by the DLD (long word load) and the DSUB (double precision subtract) instructions, which handle 32-bit operands in a single cycle. For the upper half of a partial remainder, the SUBB (SUB with borrow) instruction uses the borrow bit generated in the lower 32-bit partial remainder. Each partial remainder is stored in two consecutive memory locations by a DST.

*Example 6–6. 64-Bit Subtraction*

```

;

;      SUB    @Y3,16,A   ;A = X3 X2 - Y3 Y2 - (inv C)
;      DST    A,@W3
;      RET

```

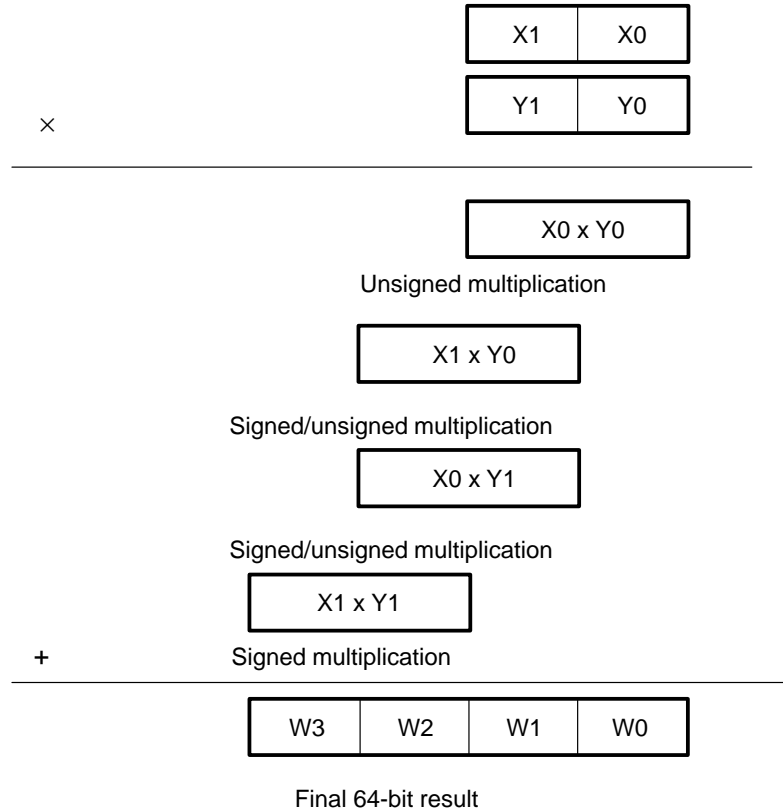

## 6.4.2 Multiplication

The MPYU (unsigned multiply) and MACSU (signed/unsigned multiply and accumulate) instructions can also handle extended-precision calculations.

Figure 6–3 shows how two 32-bit numbers obtain a 64-bit product. The MPYU instruction multiplies two unsigned 16-bit numbers and places the 32-bit result in one of the accumulators in a single cycle. The MACSU instruction multiplies a signed 16-bit number by an unsigned 16-bit number and accumulates the result in a single cycle. Efficiency is gained by generating partial products of the 16-bit portions of a 32-bit (or larger) value instead of having to split the value into 15-bit (or smaller) parts.

Figure 6–3. 32-Bit Multiplication

The program in Example 6–7 shows that a multiply of two 32-bit integer numbers requires one multiply, three multiply/accumulates, and two shifts. The product is a 64-bit integer number. Note in particular, the use of MACSU, MPYU and LD instructions. The LD instruction can perform a right-shift in the accumulator by 16 bits in a single cycle.

Example 6–8 performs fractional multiplication. The operands are in Q31 format, while the product is in Q30 format.

## 6.5 Floating-Point Arithmetic

In fixed-point arithmetic, the binary point that separates the integer from the fractional part of the number is fixed at a certain location. For example, if a 32-bit number places the binary point after the most significant bit (which is also the sign bit), only fractional numbers (numbers with absolute values less than 1), can be represented. The fixed-point system, although simple to implement in hardware, imposes limitations in the dynamic range of the represented number. You can avoid this difficulty by using floating-point numbers.

A floating-point number consists of a mantissa,  $m$ , multiplied by a base,  $b$ , raised to an exponent,  $e$ , as follows:

$$m * b^e$$

To implement floating-point arithmetic on the '54x, operands must be converted to fixed-point numbers and then back to floating-point numbers. Fixed-point values are converted to floating-point values by normalizing the input data.

Floating-point numbers are generally represented by mantissa and exponent values. To multiply two numbers, add their mantissas, multiply the exponents, and normalize the resulting mantissa. For floating-point addition, shift the mantissa so that the exponents of the two operands match. Left-shift the lower-power operand by the difference between the two exponents. Add the exponents and normalize the result.

Figure 6–4 illustrates the IEEE standard format to represent floating-point numbers. This format uses sign-magnitude notation for the mantissa, and the exponent is biased by 127. In a 32-bit word representing a floating-point number, the first bit is the sign bit, represented by  $s$ . The next eight bits correspond to the exponent, which is expressed in an offset-by-127 format (the actual exponent is  $e-127$ ). The following 23 bits represent the absolute value of the mantissa, with the most significant 1 implied. The binary point is placed after this most significant 1. The mantissa, then, has 24 bits.

Figure 6–4. IEEE Floating-Point Format

The values of the numbers represented in the IEEE floating-point format are as follows:

$$(-1)^s * 2^{e-127} * (01.f) \quad \text{If } 0 < e < 255$$

Special Cases:

$$(-1)^s * 0.0 \quad \text{If } e = 0, \text{ and } f = 0 \text{ (zero)}$$

$$(-1)^s * 2^{-126} * (0.f) \quad \text{If } e = 0 \text{ and } f \neq 0 \text{ (denormalized)}$$

$$(-1)^s * \text{infinity} \quad \text{If } e = 255 \text{ and } f = 0 \text{ (infinity)}$$

$$\text{NaN (not a number)} \quad \text{If } e = 255 \text{ and } f \neq 0$$

Example 6–9 through Example 6–11 illustrate how the '54x performs floating-point addition, multiplication, and division.

### Example 6–9. Add Two Floating-Point Numbers

```

*;*****
*; FLOAT_ADD - add two floating point numbers
*; Copyright (c) 1993-1994 Texas Instruments Incorporated
*; NOTE: The ordering of the locals are placed to take advantage of long word
*; loads and stores which require the hi and low words to be at certain addresses.
*; Any future modifications which involve the stack must take this quirk into
*; account
*;*****
*;*****
;Operand 1 (OP1) and Operand (OP2) are each packed into sign, exponent, and the
;words of mantissa. If either exponent is zero special case processing is initiated.
;In the general case, the exponents are compared and the mantissa of the lower
;exponent is renormalized according to the number with the larger exponent. The
;mantissas are also converted to a two's complement format to perform the actual
;addition. The result of the addition is then renormalized with the corresponding
;adjustment in the exponent. The resulting mantissa is converted back to its
;original sign-magnitude format and the result is repacked into the floating point
;representation.

Example 6–10. Multiply Two Floating-Point Numbers

```

*;*****
*; Float_MUL - multiply two floating point numbers
*; Copyright (c) 1993-1994 Texas Instruments Incorporated
*;*****
*;*****
*;This routine multiplies two floating point numbers. OP1 and OP2 are each unpacked
;into sign, exponent, and two words of mantissa. If either exponent is zero
;special case processing is initiated. The exponents are summed. If the result is
;less than zero underflow has occurred. If the result is zero, underflow may have
;occurred. If the result is equal to 254 overflow may have occurred. If the result
;is greater than 254 overflow has occurred. Underflow processing returns a value
;of zero. Overflow processing returns the largest magnitude value along with the
;appropriate sign. If no special cases are detected, a 24x24-bit multiply is
;executed. The result of the exclusive OR of the sign bits, the sum of the
;exponents and the ;24 bit truncated mantissa are packed and returned

*Example 6–11. Divide a Floating-Point Number by Another*

```

*;*****
*; FLOAT_DIV - divide two floating point numbers
*; Copyright (c) 1993–1994 Texas Instruments Incorporated
*;*****
;Implementation: OP1 and OP2 are each unpacked into sign, exponent, and two words
;of mantissa. If either exponent is zero special case processing is initiated.
;The difference of the exponents are taken. IF the result is less than zero underflow
;has occurred. If the result is zero, underflow may have occurred. If the result
;is equal to 254 overflow may have occurred. If the result is greater than 254
;overflow has occurred.
; Underflow processing returns a value of zero. Overflow processing returns the
;largest magnitude value along with the appropriate sign. If no special cases are
;detected, a 24x24-bit divide is ;executed. The result of the exclusive OR of the
;sign bits, the difference of the exponents and the 24 bit truncated mantissa are
;packed and returned.

BC     overflow,AGT      ; branch to overflow is exp > 127
*
* ;*****
* ;          DIVISION
* ; Division is implemented by parts. The mantissas for both OP1 and OP2 are left shifted
* ; in the 32 bit field to reduce the effect of secondary and tertiary contributions to
* ; the final result. The left shifted results are identified as OP1'HI, OP1'LO, OP2'HI,
* ; and OP2'LO where OP1'HI and OP2'HI have the xx most significant bits of the mantissas
* ; and OP1'LO and OP2'LO contain the remaining bits * of each mantissa. Let QHI and QLO
* ; represent the two portions of the resultant mantissa. Then
*
*      
$$QHI + QLO = \frac{OP1'HI + OP1'LO}{OP2'HI + OP2'LO} = \frac{OP1'HI + OP1'LO}{OP2'HI} * \frac{1}{\left(1 + \frac{OP2'LO}{OP2'HI}\right)}$$

*
* ; Now let X = OP2'LO/OP2'HI
* ; Then by Taylor's Series Expansion
*
*      
$$\frac{1}{(1+x)} = 1-x + x^2-x^3 + \dots$$

*
* ; Since OP2'HI contains the first xx significant bits of the OP2 mantissa,*
* X = OP2'LO/OP2'HI < 2-yy* ; Therefore the X2 term and all subsequent terms are less
* than the least significant
* bit of the 24-bit result and can be dropped. The result then becomes
*
*      
$$QHI + QLO = \frac{OP1'HI + OP1'LO}{OP2'HI + OP2'LO} * \left(1 - \frac{OP2'LO}{OP2'HI}\right)$$

*
*      
$$= (QHI + QLO) * \left(1 - \frac{OP2'LO}{OP2'HI}\right)$$

*
* ; where Q'HI and Q'LO represent the first approximation of the result. Also since
* ; Q'LO and OP2'LO/OP2'HI are less significant the 24th bit of the result, this
* ; product term can be dropped so
*
*      
$$QHI + QLO = \frac{OP1'HI + OP1'LO}{OP2'HI + OP2'LO} = \frac{OP1'HI + OP1'LO}{OP2'HI} * \frac{1}{\left(1 + \frac{OP2'LO}{OP2'HI}\right)}$$

## 6.6 Logical Operations

DSP-application systems perform many logical operations, including bit manipulation and packing and unpacking data. A digital modem uses a scrambler and a descrambler to perform bit manipulation. The input bit stream is in a packed format of 16 bits. Each word is unpacked into 16 words of 16-bit data, with the most significant bit (MSB) as the original input bit of each word. The unpack buffer contains either 8000h or 0000h, depending upon the bit in the original input-packed 16-bit word. The following polynomial generates a scrambled output, where the  $\oplus$  sign represents modulus 2 additions from the bitwise exclusive OR of the data values:

$$\text{Scrambler output} = 1 \oplus x^{-18} \oplus x^{-23}$$

The same polynomial sequence in the descrambler section reproduces the original 16-bit input sequence. The output of the descrambler is a 16-bit word in packed format.

# Application-Specific Examples

---

---

---

---

This chapter shows examples of typical applications for the '54x. Since this DSP is widely used for speech coding and telecommunications, the applications show how some aspects of these functions are implemented.

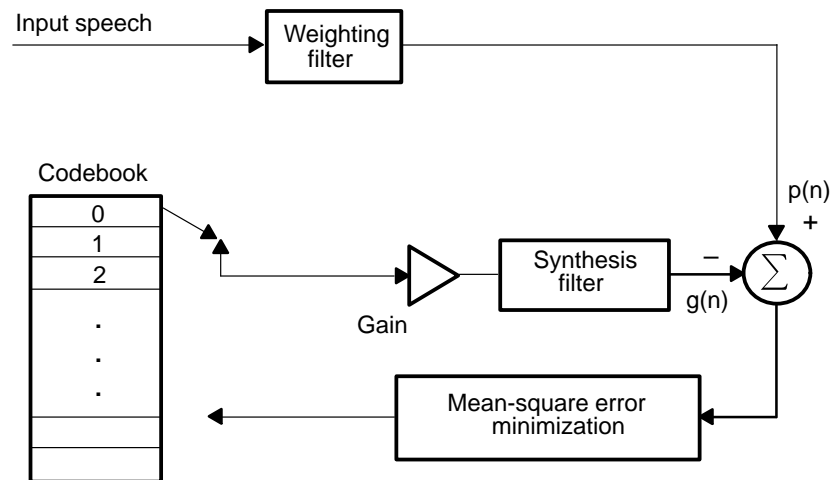

<b>Topic</b>	<b>Page</b>
7.1 Codebook Search for Excitation Signal in Speech Coding .....	7-2
7.2 Viterbi Algorithm for Channel Decoding .....	7-5

## 7.1 Codebook Search for Excitation Signal in Speech Coding

A code-excited linear predictive (CELP) speech coder is widely used for applications requiring speech coding with a bit rate under 16K bps. The speech coder uses a vector quantization technique from codebooks to an excitation signal. This excitation signal is applied to a linear predictive-coding (LPC) synthesis filter. To obtain optimum code vectors from the codebooks, a codebook search is performed, which minimizes the mean-square error generated from weighted input speech and from the zero-input response of a synthesis filter. Figure 7–1 shows a block diagram of a CELP-based speech coder.

Figure 7–1. CELP-Based Speech Coder

To locate an optimum code vector, the codebook search uses Equation 7–1 to minimize the mean-square error.

Equation 7–1. Optimum Code Vector Localization

$$E_i = \sum_{i=0}^{N-1} [p(n) - \gamma_i g_i(n)]^2 \quad N : \text{Subframe}$$

The variable  $p(n)$  is the weighted input speech,  $g_i(n)$  is the zero-input response of the synthesis filter, and  $\gamma_i$  is the gain of the codebook.

The cross-correlation ( $c_i$ ) of  $p(n)$  and  $g_i(n)$  is represented by Equation 7–2. The energy ( $G_i$ ) of  $g_i(n)$  is represented by Equation 7–3.

Equation 7–2. Cross Correlation Variable ( $c_i$ )

$$c_i = \sum_{n=0}^{N-1} g_i * p(n)$$

Equation 7–3. Energy Variable ( $G_i$ )

$$G_i = \sum_{n=0}^{N-1} g_i^2$$

Equation 7–1 is minimized by maximizing  $c_i^2 / G_i$ . Therefore, assuming that a code vector with  $i = \text{opt}$  is optimal, Equation 7–4 is always met for any  $i$ . The codebook search routine evaluates this equation for each code vector and finds the optimum one.

Equation 7–4. Optimal Code Vector Condition

$$\left( \frac{c_i^2}{G_i} \right) \leq \left( \frac{c_{\text{opt}}^2}{G_{\text{opt}}} \right)$$

Example 7–1 shows the implementation algorithm for codebook search on '54x. The square (SQUR), multiply (MPYA), and conditional store (SRCCD, STRCD, SACCD) instructions are used to minimize the execution cycles. AR5 points to  $c_i$  and AR2 points to  $G_i$ . AR3 points to the locations of  $G_{\text{opt}}$  and  $c_{\text{opt}}^2$ . The value of  $i(\text{opt})$  is stored at the location addressed by AR4.

### 7.2 Viterbi Algorithm for Channel Decoding

Convolutional encoding with the Viterbi decoding algorithm is widely used in telecommunication systems for error control coding. The Viterbi algorithm requires a computationally intensive routine with many add-compare-select (ACS) iterations. The '54x can perform fast ACS operations because of dedicated hardware and instructions that support the Viterbi algorithm on chip. This implementation allows the channel decoder and the equalizer in communication systems to be used efficiently.

In the global system for mobile communications (GSM) cellular radio, the polynomials in Equation 7-5 are used for convolutional encoding.

Equation 7-5. Polynomials for Convolutional Encoding

$$G1(D) = 1 + D^3 + D^4 \qquad G2(D) = 1 + D + D^3 + D^4$$

This convolutional encoding can be represented in a trellis diagram, which forms a butterfly structure as shown in Figure 7-2. The trellis diagram illustrates all possible transformations of convolutional encoding from one state to another, along with their corresponding path states. There are 16 states, or eight butterflies, in every symbol time interval. Two branches are input to each state. Decoding the convolutional code involves finding the optimal path by iteratively selecting possible paths in each state through a predetermined number of symbol time intervals. Two path metrics are calculated by adding branch metrics to two old-state path metrics and the path metric (J) for the new state is selected from these two path metrics.

Figure 7-2. Butterfly Structure of the Trellis Diagram

Equation 7–6 defines a branch metric.

*Equation 7–6. Branch Metric*

$$M = SD(2^i) * B(J,0) + SD(2^{i+1}) * B(J,1)$$

$SD(2^i)$  is the first symbol that represents a soft-decision input and  $SD(2^{i+1})$  is the second symbol.  $B(J,0)$  and  $B(J,1)$  correspond to the code generated by the convolutional encoder as shown in Table 7–1.

*Table 7–1. Code Generated by the Convolutional Encoder*

<b>J</b>	<b>B(J,0)</b>	<b>B(J,1)</b>
0	1	1
1	–1	–1
2	1	1
3	–1	–1
4	1	–1
5	–1	1
6	1	–1
7	–1	1

The '54x can compute a butterfly quickly by setting the ALU to dual 16-bit mode. To determine the new path metric (J), two possible path metrics from  $2^J$  and  $2^{J+1}$  are calculated in parallel with branch metrics (M and –M) using the DADST instruction. The path metrics are compared by the CMPS instruction.

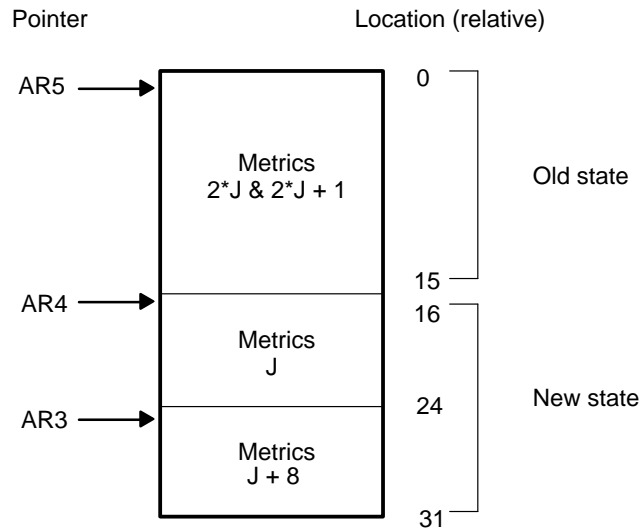

To calculate the new path metric (J+8), the DSADT instruction calculates two possible path metrics using branch metrics and old path metrics stored in the upper half and lower half of the accumulator. The CMPS instruction determines the new path metric.

The CMPS instruction compares the upper word and the lower word of the accumulator and stores the larger value in memory. The 16-bit transition register (TRN) is updated with every comparison so you can track the selected path metric. The TRN contents must be stored in memory locations after processing each symbol time interval. The back-track routine uses the information in memory locations to find the optimal path.

Example 7–2 shows the Viterbi butterfly macro. A branch metric value is stored in T before calling the macro. During every butterfly cycle, two macros prevent T from receiving opposite sign values of the branch metrics. Figure 7–3 illustrates pointer management and the storage scheme for the path metrics used in Example 7–2.

In one symbol time interval, eight butterflies are calculated for the next 16 new states. This operation repeats over a number of symbol time intervals. At the end of the sequence of time intervals, the back-track routine is performed to find the optimal path out of the 16 paths calculated. This path represents the bit sequence to be decoded.

# Bootloader

---

---

---

---

The bootloader lets you load and execute programs received from a host processor, EPROMs, or other standard memory devices. The '54x devices provide different ways to download the code to accommodate various system requirements. Some applications use a serial interface. If the code exists in external ROM, a parallel interface is appropriate. This chapter uses the '542 as a reference platform for HPI bootloader option platform and '541 for other bootloader options available on '54x.

<b>Topic</b>	<b>Page</b>
<b>8.1 Boot Mode Selection</b> .....	<b>8-2</b>
<b>8.2 Host Port Interface (HPI) Boot Loading Sequence</b> .....	<b>8-4</b>
<b>8.3 16-Bit/8-Bit Parallel Boot</b> .....	<b>8-5</b>
<b>8.4 I/O Boot</b> .....	<b>8-8</b>
<b>8.5 Standard Serial Boot</b> .....	<b>8-10</b>
<b>8.6 Warm Boot</b> .....	<b>8-12</b>

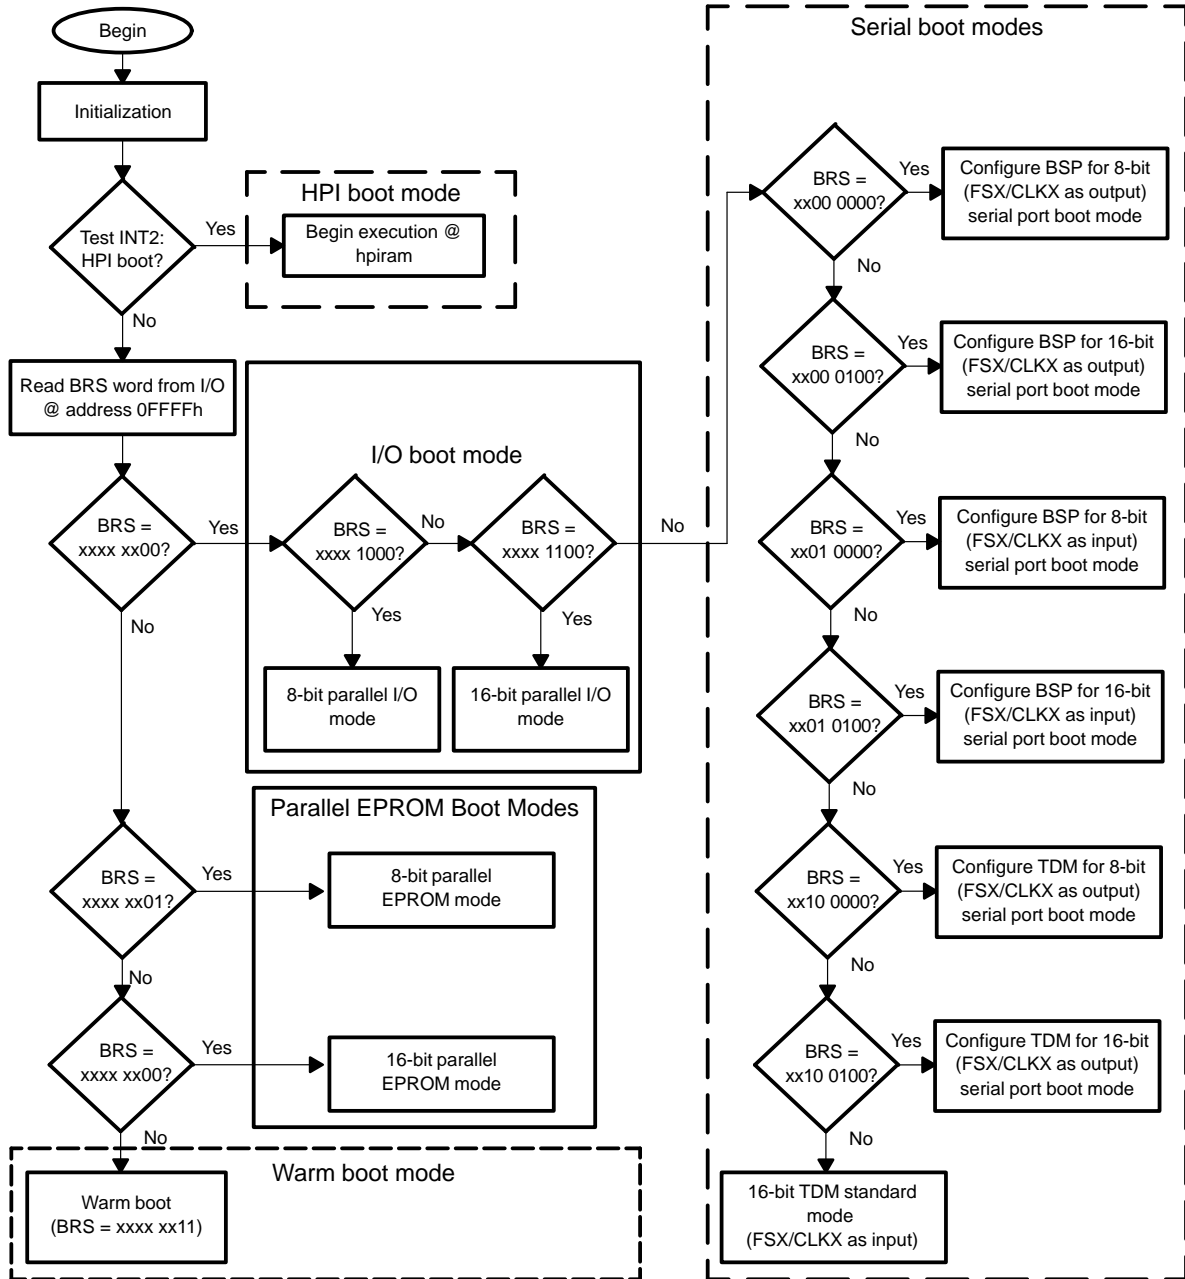

## 8.1 Boot Mode Selection

Execution begins at location FF80h of the on-chip ROM if the  $\overline{\text{MP/MC}}$  pin of the '54x is sampled low during a hardware reset. This location contains a branch instruction to start the bootloader program that is factory-programmed in ROM. This program sets up the CPU status registers before initiating the bootstrap. Interrupts are globally disabled ( $\text{INTM} = 1$ ) and internal dual-access and single-access RAMs are mapped into program/data space ( $\text{OVLY} = 1$ ). Seven wait states are initialized for all the program and data spaces. The size of the external memory bank is set to 4K words. It uses one latency cycle when switching between program and data space.

The boot routine reads the I/O port address 0FFFFh by driving the I/O strobe ( $\overline{\text{IS}}$ ) signal low. The lower eight bits of the word read from I/O port address 0FFFFh specify the mode of transfer. The boot routine selection (BRS) word determines the boot mode. The BRS word uses a source (SRC) field when in parallel EPROM mode and an entry address (ADDR) field when using a warm boot (see Section 8.6, *Warm Boot* on page 8-12). The six least significant bits and the configuration of CLKX and FSX pins determine whether to use the 8- or 16-bit bootstrap serial boot option. The BRS word also determines the 8- or 16-bit parallel I/O mode.

The host port interface (HPI) uses interrupt 2 to bootstrap (INT2). If INT2 is not latched, the boot routine skips HPI bootstrap mode (see Section 8.2, *Host Port Interface (HPI) Bootloading Sequence* on page 8-4). It reads the lower eight bits from the I/O address, 0FFFFh, to determine the boot mode. Figure 8-1 illustrates the boot mode selection process.

Figure 8–1. Boot Mode Selection Process

## 8.2 Host Port Interface (HPI) Boot Loading Sequence

The HPI is an 8-bit parallel port that interfaces a host processor to the '542. The host processor and the '542 exchange information via on-chip, shared memory. The host interrupts the CPU by writing to the HPI control register (HPIC). The CPU interrupts the host by asserting the host interrupt ( $\overline{\text{HINT}}$ ) signal. The host can acknowledge or clear this signal. The signal determines whether the HPI boot option is selected by asserting  $\overline{\text{HINT}}$  low. This signal is tied to the external interrupt  $\overline{\text{INT2}}$  input pin if HPI boot mode is selected. (Instead of tying  $\overline{\text{HINT}}$  to  $\overline{\text{INT2}}$ , you can send a valid interrupt to the  $\overline{\text{INT2}}$  input pin within 30 CLOCKOUT cycles after the '542 fetches the reset vector.)

Asserting  $\overline{\text{HINT}}$  low sets the corresponding interrupt flag register (IFR) bit. The bootloader waits for 20 CLKOUT cycles after asserting  $\overline{\text{HINT}}$  and reads bit 2 of IFR. If the bit is set (indicating that  $\overline{\text{INT2}}$  is recognized), the bootloader transfers control to the start address of the on-chip HPI RAM (1000h in program space) and executes code from that point. If bit 2 of the IFR is not set, the boot routine skips HPI boot mode and reads BRS from the I/O address, 0FFFFh, in I/O space. The lower eight bits of this word specify the mode of transfer. The bootloader ignores the rest of the bits.

If HPI boot mode is selected, the host must download the code to on-chip HPI RAM before the HPI brings the device out of reset. The bootloader keeps HPI in shared-access mode ( $\text{SMODE} = 1$ ) during the entire operation. Once  $\overline{\text{HINT}}$  is asserted low by the bootloader, it stays low until a host controller clears it by writing to HPIC.

### 8.3 16-Bit/8-Bit Parallel Boot

The parallel boot option is used when the code is stored in EPROMs (8 or 16 bits wide). The code is transferred from data to program memory. The six most significant bits (MSBs) of the source address are specified by the SRC field of the BRS word, as shown in Figure 8–2.

Figure 8–2. 16-Bit EPROM Address Defined by SRC Field

15	10	9	8	7	6	5	4	3	2	1	0
SRC		0	0	0	0	0	0	0	0	0	0

**Note:** SRC = Source address

If 16-bit parallel mode is selected, data is read in 16-bit words from the source address and incremented by 1 after every read operation. The destination address and the length of the code are specified by the first two 16-bit words. The length is defined as:

$$\text{Length} = \text{number of 16-bit words to be transferred} - 1$$

The number of 16-bit words specified by length does not include the first two words read (destination and length parameters), starting from the source address. This is shown in Figure 8–3. The code is transferred from data memory (source address) to program memory (destination address). At least a 10-cycle delay occurs between a read from EPROM and a write to the destination address. This ensures that if the destination is external memory, like fast SRAM, there is enough time to turn off the source memory (EPROM) before the write operation is performed. After the code is transferred to program memory, the '541 branches to the destination address. This occurs for both for 16-bit and 8-bit parallel boot options.

Code word (N) <sub>16</sub>	

- Notes:**
- 1) Destination <sub>16</sub> = 16-bit destination
  - 2) Length <sub>16</sub> = 16-bit word that specifies the length of the code (N) that follows it
  - 3) Code word (N) <sub>16</sub> = N 16-bit words to be transferred

If the 8-bit parallel boot option is selected (see Figure 8–4), two consecutive memory locations (starting at the source address) are read to make one 16-bit word. The high-order byte must be followed by the low-order byte. Data is read from the lower eight data lines, ignoring the upper byte on the data bus. The destination address is a 16-bit word that constitutes the address in program space where the boot code is transferred. The length is defined as:

$$\begin{aligned} \text{Length} &= \text{number of 16-bit words to be transferred} - 1 \\ &= (\text{number of bytes to be transferred} / 2) - 1 \end{aligned}$$

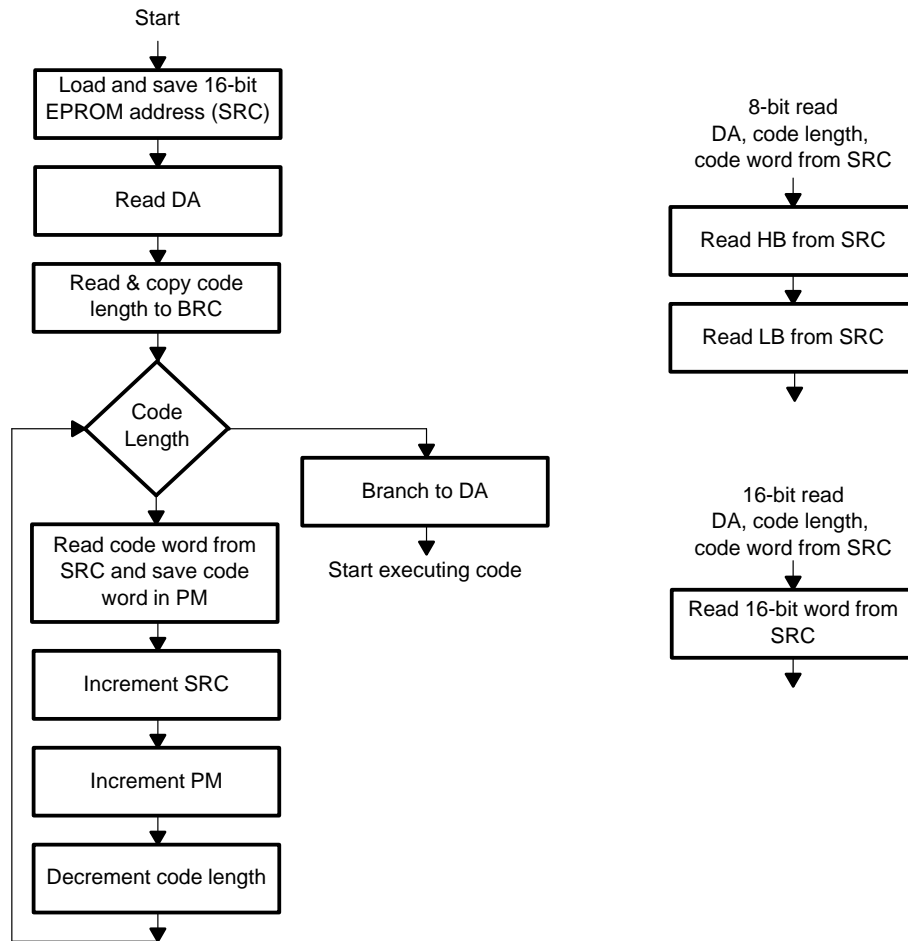

*Figure 8–4. Data Read During 8-Bit Parallel Boot*

7	0
Destination <sub>h</sub>	
Destination <sub>l</sub>	
Length <sub>h</sub> = N – 1	
Length <sub>l</sub> = N – 1	
Code word (1) <sub>h</sub>	
Code word (1) <sub>l</sub>	
.	
.	
Code word (N) <sub>h</sub>	
Code word (N) <sub>l</sub>	

- Notes:**
- 1) Destination<sub>h</sub> and Destination<sub>l</sub> represent high and low bytes of destination address
  - 2) Length<sub>h</sub> and Length<sub>l</sub> represent high and low bytes of a 16-bit word that specifies the length N of the code that follows it.
  - 3) N<sub>h</sub> and N<sub>l</sub> bytes constitute N words to be transferred.

Figure 8–5 shows the parallel boot sequence, both for the 16- and 8-bit options.

Figure 8–5. 8-Bit/16-Bit Parallel Boot

## 8.4 I/O Boot

The I/O boot mode provides asynchronous transfer code from I/O address 0h to internal/external program memory. Each word can be 16 or 8 bits long. The '541 communicates with external devices using the  $\overline{\text{BIO}}$  and XF handshake lines. The handshake protocol shown in Figure 8–6 is required to successfully transfer words from I/O address 0h.

Figure 8–6. Handshake Protocol

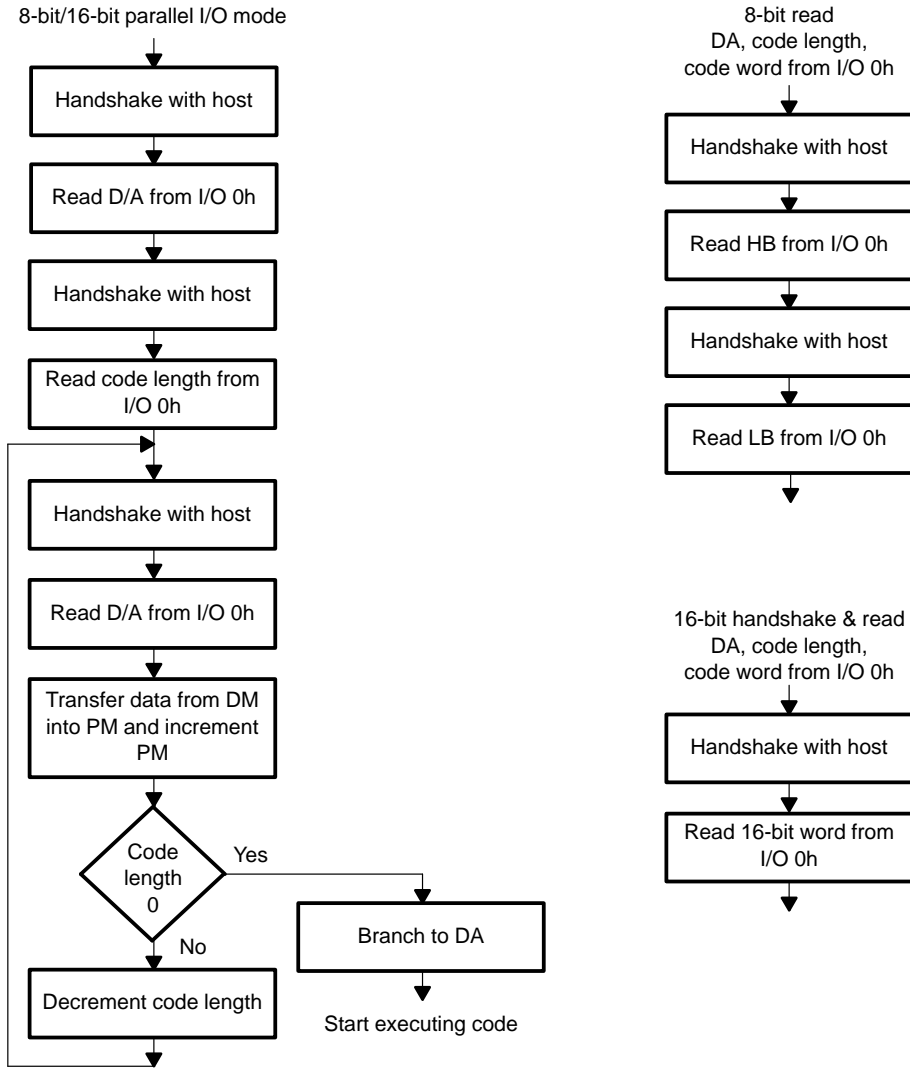

Figure 8–6 shows a data transfer initiated by the host, which drives the  $\overline{\text{BIO}}$  pin low. When  $\overline{\text{BIO}}$  goes low, the '541 inputs data from I/O address 0h, drives the XF pin high to indicate to the host that the data has been received, and writes the input data to the destination address. The '541 then waits for the  $\overline{\text{BIO}}$  pin to go high before driving the XF pin low. The low status of the XF line can be polled by the host for the next data transfer.

If 8-bit transfer mode is selected, the lower eight data lines are read from I/O address, 0h. The upper byte on the data bus is ignored. The '541 reads two 8-bit words to form a 16-bit word. The low byte of each 16-bit word must follow the high byte. Figure 8–7 shows the I/O boot sequence, both for the 16- and 8-bit options.

For both 8- and 16-bit I/O, the first two 16-bit words received by the '541 must be the destination and length of the code, respectively. A minimum delay of 10 clock cycles occurs between the rising edge of XF and the write to the destination address. This allows the processor sufficient time to turn off its data buffers before the '541 initiates the write operation if the destination is external memory. The '541 accesses the external bus only when XF is high.

Figure 8-7. 8-Bit/16-Bit I/O Boot Mode

## 8.5 Standard Serial Boot

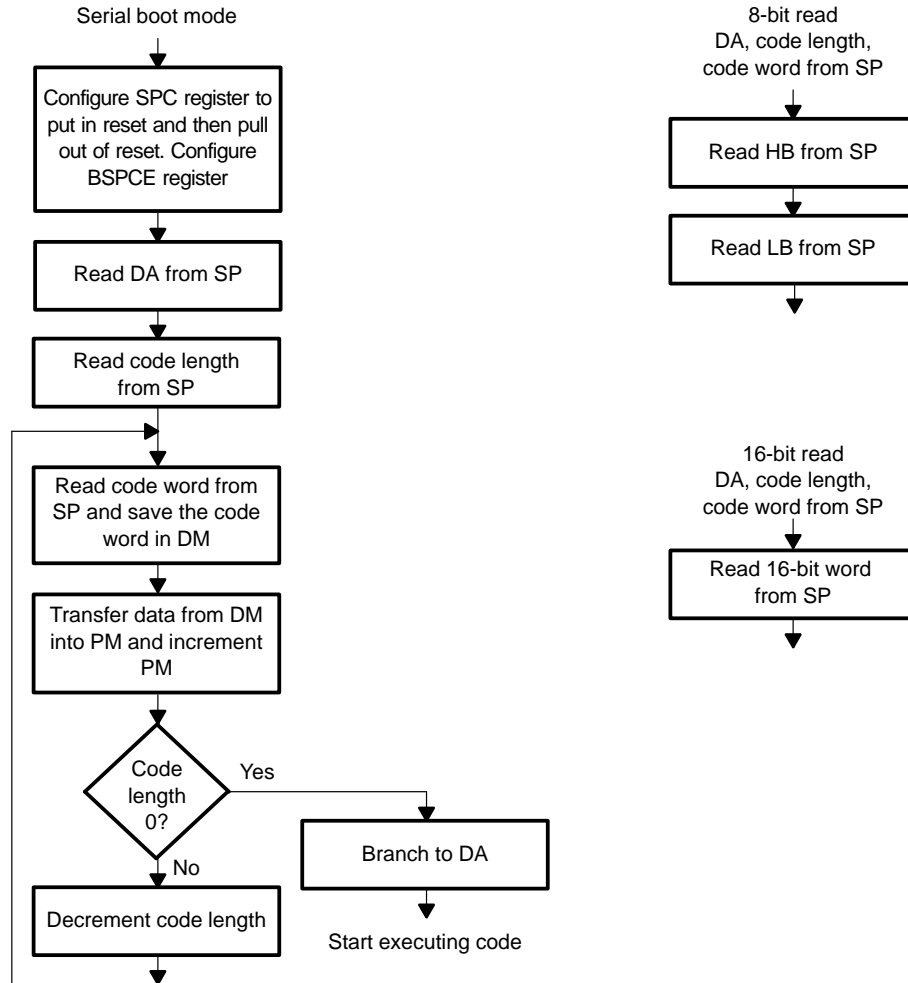

The '541 serial boot option can use either the buffered serial port (BSP) or time-division multiplexed (TDM) serial port in standard mode during booting. Eight modes are available for the serial boot option (see Figure 8–1, *Boot Mode Selection Process*, on page 8-3). The word length (8- or 16-bit) and the configuration of the CLKX/FSX pins determines the correct mode to use. For 8-bit operation, set the following bits:

- Receive reset signal,  $\overline{RRST}$  (to take serial port 0 out of reset)
- Transmit mode bit, TXM
- Clock mode bit, MCM (so that CLKX is driven by an on-chip clock source)
- Frame sync mode bit, FSM (frame sync pulses must be supplied externally on the FSR pin)
- Format bit, FO (so that data is transferred in an 8-bit length)

This translates to a value of 3Ch to the SPC register, which puts the serial port in reset. The  $\overline{RRST}$  and  $\overline{XRST}$  of SPC register are set to 1 to take the serial port out of reset for configuring CLKX/FSX as output pins in 8-bit mode. Then a value of FCh is written to the SPC register for 16-bit mode, FO = 0. This writes 38h to the SPC register to put the serial port in reset. It also writes a 1 to both  $\overline{RRST}$  and  $\overline{XRST}$  to pull the serial port register out of reset and configure CLKX/FSX as output pins, and a value of F8h is written to the SPC register.

To drive the CLKX and FSX pins as inputs, the MCM and TXM bits are disabled and the serial port is configured for 8- and 16-bit mode options. The external flag, XF, sends a signal that the '541 is ready to respond to and receive from the serial port. The XF flag is set high at reset and is driven low to initiate reception. No frame sync pulses can appear on FSR before XF goes low. For the buffered serial port, the BSP control extension register (BSPCE) is initialized to set the CLKX to 1/4 of the CLKOUT signal. Figure 8–8 shows the serial boot sequence.

Figure 8–8. Serial Boot Mode

## 8.6 Warm Boot

The '541 transfers control to the entry address if the warm boot option is specified. The warm boot option can be used after a warm device reset or if the program has already been transferred to internal or external memory by other means, such as a direct memory access (DMA). For a warm boot, the six MSBs at the entry point of the code are specified by the SRC or ADDR fields of the BRS word, as shown in Figure 8–9.

Figure 8–9. Warm Boot Address Specified in BRS Word

15	10	9	8	7	6	5	4	3	2	1	0
ADDR	0	0	0	0	0	0	0	0	0	0	0

**Note:** ADDR = 6-bit page address

# Host–Target Communication

---

---

---

---

This chapter describes the communication interface between the '54x EVM and its host. The system passes data between the target and host, while maintaining real-time operation. The system can be driven by interrupts, polled, or a mixture of the two.

<b>Topic</b>	<b>Page</b>
<b>9.1 Communication Channels .....</b>	<b>9-2</b>
<b>9.2 Handshake and Data Transfer .....</b>	<b>9-6</b>

### 9.1 Communication Channels

The host communicates to the '54x EVM via 38 16-bit I/O locations. Each I/O location is defined by an offset to an I/O page 0 address, shown in Table 9–1. There are two independent communication channels, A and B, through which the host and target can communicate. The status/control registers on both the host and target provide system-level control and status information.

*Table 9–1. '54x EVM Host-Interface Register Usage*

I/O Offset From Base Address	Register	Size	Register Type
0x0800	Channel A	16	Read/write
0x0804	Channel B	16	Read/write
0x0808	Status/control	16	Read/write

The host writes to channel A (offset 0x0800) and overwrites the current value. An interrupt 1 ( $\overline{INT1}$ ) signal is generated to the target, which sets the channel A transmit status bit, AXST, to 1 in the host control register (HCR) and sets the channel A receive status bit, ARST, to 1 in the target control register (TCR). The host reads from the same location, which clears the ARST bit in HCR and clears AXST in TCR. Channel B is a 64-word deep, bidirectional FIFO register that transfers both data and commands. Host write to 0x0804 is buffered by the FIFO. Data is ignored if the FIFO is full. Figure 9–1 shows the HCR and Table 9–2 describes the bits.

*Figure 9–1. Host Control Register (HCR) Diagram*

Table 9–2. Host Control Register (HCR) Bit Summary

Bit	Name	Description																		
15	RESET	Software reset. If RESET = 1, the target processor and emulation logic are reset but the host/target communication flags are not reset.																		
14	MP/MC	Microprocessor/microcomputer mode select. The EVM powers up in microcomputer mode.																		
13	BTIE	Channel B target interrupt enable. If BTIE = 1, channel A receive conditions generate a host interrupt.																		
12	ATIE	Channel A target interrupt enable. If ATIE = 1, channel A receive conditions generate a host interrupt.																		
11	HBIO	Host BIO input to target processor																		
10	BRST2	Channel B receive status bit 2. If BRST2 =1, the target has written to channel B, forcing an interrupt. The BRST2 flag is cleared when the host reads its channel B.																		
9–8	BRST	Channel B receive status:																		
<table border="1"> <thead> <tr> <th colspan="3">BRST</th> </tr> <tr> <th>Bit 9</th> <th>Bit 8</th> <th>Channel B Receive Status</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Buffer empty</td> </tr> <tr> <td>0</td> <td>1</td> <td>Buffer less than half full</td> </tr> <tr> <td>1</td> <td>0</td> <td>Buffer half or more than full</td> </tr> <tr> <td>1</td> <td>1</td> <td>Buffer full</td> </tr> </tbody> </table>			BRST			Bit 9	Bit 8	Channel B Receive Status	0	0	Buffer empty	0	1	Buffer less than half full	1	0	Buffer half or more than full	1	1	Buffer full
BRST																				
Bit 9	Bit 8	Channel B Receive Status																		
0	0	Buffer empty																		
0	1	Buffer less than half full																		
1	0	Buffer half or more than full																		
1	1	Buffer full																		
7	REV1	Card revision status bit 1																		
6	REV0	Card revision status bit 0																		
5	XF	External flag from target processor (status)																		
4	BIO	BIO input to target processor																		

*Table 9–2. Host Control Register (HCR) Bit Summary (Continued)*

Bit	Name	Description																		
3–2	BXST	Channel B transmit status:																		
<table border="1"> <thead> <tr> <th colspan="3">BXST</th> </tr> <tr> <th>Bit 3</th> <th>Bit 2</th> <th>Channel B Transmit Status</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Buffer empty</td> </tr> <tr> <td>0</td> <td>1</td> <td>Buffer less than half full</td> </tr> <tr> <td>1</td> <td>0</td> <td>Buffer half or more than full</td> </tr> <tr> <td>1</td> <td>1</td> <td>Buffer full</td> </tr> </tbody> </table>			BXST			Bit 3	Bit 2	Channel B Transmit Status	0	0	Buffer empty	0	1	Buffer less than half full	1	0	Buffer half or more than full	1	1	Buffer full
BXST																				
Bit 3	Bit 2	Channel B Transmit Status																		
0	0	Buffer empty																		
0	1	Buffer less than half full																		
1	0	Buffer half or more than full																		
1	1	Buffer full																		
1	ARST	Channel A receive status. If ARST = 1, the target has written to its channel A register. The ARST flag is cleared when the host reads channel A.																		
0	AXST	Channel A transmit status. If AXST = 1, host has written to its channel A register. The AXST flag is cleared when the target reads channel A.																		

The EVM supports two communication channels, configured as six I/O ports for host/target communication and 16 I/O ports for user expansion. Channel A is a single 16-bit bidirectional register mapped into two I/O port locations. Channel B is a single, bidirectional, 64-deep, FIFO buffer that is mapped into two I/O port locations. A status I/O port provides target control and general-purpose control, status, and discrete-bit I/O. Figure 9–3 shows the TCR and Table 9–3 describes the bits.

*Figure 9–2. '54x EVM Port Usage*

Port Address	Name	Usage
0x0010	Channel A	Communications
0x0012	Channel B	Communications
0x0014	Status	Target status/control

*Figure 9–3. Target Control Register (TCR) Diagram*

Bit 3	Bit 2	Channel B Transmit Status																		
0	0	Buffer empty																		
0	1	Buffer less than half full																		
1	0	Buffer half or more than full																		
1	1	Buffer full																		
1	ARST	Channel A receive status. If ARST = 1, the host has written to its channel A register. The ARST flag is cleared when the target reads channel A.																		
0	AXST	Channel A transmit status. If AXST = 1, target has written to its channel A register. The AXST flag is cleared when the host reads channel A.																		

**Note:** For further register and I/O information, see the *TMS320C54x Evaluation Module Technical Reference*.

## 9.2 Handshake and Data Transfer

Example 9–1 through Example 9–4 show how to communicate between the host and the target through both channels, A and B. The communication involves two steps: a handshake and a data transfer. Channel A sends commands between the host and the target and channel B uses the FIFO buffer to transfer data, either 64 or 32 words at a time. A buffer of 256 samples is transferred from target to the host. Data is sent 32 words at a time from the target, except for the first FIFO, where the first 64 words are sent to the host. The data is transferred from the target to the FIFO whenever an  $\overline{\text{INT1}}$  signal occurs. This is generated when the host writes to channel A. The XF line on the host control sets up a handshake between the host and the target. Figure 9–4 illustrates the sequence of events in a handshake and Figure 9–5 illustrates the sequence of events in a data transfer.

**Example 9–1. Handshake — Target Action (Continued)**

```

; Functional Description
;
; This initiates the handshake between the host(PC) and the target (DSP).
; The host writes a command to CH A. This generates an INT1 on the target.
; The AXST bit on HCR is set to 1.The INT1 bit in IFR is polled if it is set
; then it is cleared to clear pending interrupts. The FIFO is cleared
; by reading from the FIFO. The command from host is read thru CH A and ARST
; on TCR is cleared. Another command from target is written to CH A,
; which sets AXST. Also sets XF low. The host polls XF line.
; The host reads CH A which clears ARST on host side and AXST on target side.

# Application Code Examples

---

---

---

---

This chapter contains complete code examples for routines that are excerpted in previous chapters of this book. These routines have been developed using a '54x EVM platform. These programs demonstrate applications that use a host interface and run in real time. You may download them to use in developing your own applications.

<b>Topic</b>	<b>Page</b>
<b>10.1 Running the Applications .....</b>	<b>10-2</b>
<b>10.2 Application Code .....</b>	<b>10-4</b>

## 10.1 Running the Applications

The host communicates to the '54x EVM through 16-bit I/O locations. Each I/O location is defined by an offset to an I/O page 0 address. The offset used for these applications is 0x240 + 0x800 for channel A, 0x240 + 0x804 for channel B, and 0x240 + 0x808 for the target/status control register, where 0x240 is the base address of the host. Check your PC system documentation to make sure that I/O space 0x240 does not conflict with other I/O devices. If the EVM is mapped to other than space 0x240, the base addresses of the control and status registers must be modified in the file host.h.

The '54x assembler assembles code and generates object files. The linker command file links the object files and generates a file named main.out, using common object file format (COFF). You must load main.out into the EVM debugger command window with the LOAD command and compile the host software using a Borland C compiler. This generates the file, master.exe. that contains graphic routines that display data transferred from the target to the host.

To run the target application, load main.out into the EVM debugger. To start the program on the target side, press the F5 function key. If you halt the program with the escape key or use the halt command in the debugger window, the program remains in the handshake loop waiting for the host to send a command. Press the F5 function key to continue. To run the host application, execute master.exe at the DOS prompt or a window command line. When master.exe is executed by the host, it displays the message:

```
Graphics: No error. Press any key to halt.
```

When you press this key, the graphics window opens and displays data for the task the target has initiated. The default task is an oscilloscope routine. To change to a different task, go to the debugger window, halt the program, and in the command window, type:

```
e *present_command = x
```

where x = 1, 2, 3, 4, 5 or 6, and present\_command has one of the following values:

- 1 = oscilloscope
- 2 = Low-pass finite impulse response (FIR) filter using MAC instruction
- 3 = Low-pass infinite impulse response (IIR) filter using biquad sections
- 4 = Lowpass FIR filtering using FIRS instruction
- 5 = System identification using adaptive filtering with least mean squares (LMS) instruction
- 6 = 256-point real fast Fourier transform (FFT)

You can view the output of the present task in the graphics window.

To exit the host application, press F3. Communication is lost if at any time the target code is reloaded or reset in the command window while the host executable is running in the background. This means that if you attempt to reset or reload the code in the debugger window and you press F5, the computer locks up. This occurs because there is no handshake between the host and the target. To unlock, reload and run the code (press F5) on the target side. On the host side, quit the window and rerun the executable.

The adaptive filter can be tested in two steps. The initial step size  $d\_mu = 0$  in the first step. If the present task is changed at the debugger window with the command `e *present_command = 5`, runs with  $d\_mu = 0$ . Thus, the system is not identified since the coefficients of the adaptive filter are not updated. In the second step the step size can be changed by typing `e *d_mu = 0x1000` at the command window. In this case, the system is identified and the filter coefficients are adapted using the LMS algorithm. In both cases the error signal can be observed both on host and also from the output of the 'AC01.

## 10.2 Application Code

Table 10–1 lists programs appropriate for running on a target system and tells you where to look for them in this chapter.

*Table 10–1. Target Files*

<b>Title</b>	<b>File Name</b>	<b>Page</b>
Vector Table Initialization	vectors.asm	10-6
Main Program That Calls Different Functions	main.asm	10-16
Memory Allocation for Entire Application	memory.asm	10-10
Processor Initialization	init_54x.asm	10-22
Initialization of Variables, Pointers, and Buffers	prcs_int.asm	10-29
Initialization of Serial Port 1	init_ser.asm	10-33
'AC01 Initialization	init_aic.asm	10-38
'AC01 Register Configuration	aic_cfg.asm	10-42
Receive Interrupt Service Routine	rcv_int1.asm	10-46
Task Scheduling	task.asm	10-51
Echo the Input Signal	echo.asm	10-56
Low-Pass FIR Filtering Using MAC Instruction	fir.asm	10-59
Low-Pass Biquad IIR Filter	iir.asm	10-69
Low-Pass Symmetric FIR Filtering Using FIRS Instruction	sym_fir.asm	10-64
Adaptive Filtering Using LMS Instruction	adapt.asm	10-74
256-Point Real FFT Initialization	rfft.asm	10-84
Bit Reversal Routine	bit_rev.asm	10-87
256-Point Real FFT Routine	fft.asm	10-91
Unpack 256-Point Real FFT Output	unpack.asm	10-97
Compute the Power Spectrum of the Complex Output of the 256-Point Real FFT	power.asm	10-103

Table 10–2 lists programs appropriate for running on a host system and tells you where to look for them in this chapter.

*Table 10–2. Communication Interface Files*

<b>Title</b>	<b>File Name</b>	<b>Page</b>
Handshake Between Host and Target	hand_shk.asm	10-25
Interrupt 1 Service Routine	hst_int1.asm	10-111
Data Transfer from FIFO	fifo.asm	10-106
Main Function Call on Host Side	master.c	10-118
Function Calls on Host Side	host.c	10-116
Display the Data on the Screen	view2.c	10-123
Graphic Drivers Routine	graphic2.c	10-121

Example 10–28 on page 10-124 shows the linker command that links all object files together to produce a single executable COFF object module. This file establishes the memory configuration for the entire application, using the '541's memory map. Example 10–29 on page 10-127 shows the configuration of the memory map for a '541 device used by an EVM debugger.

; =====
;
; -----
; 5.1 evm_handshake
;
```

**Example 10–5. Handshake Between Host and Target (Continued)**

```

; 5.2 Functional Description
;
; This initiates the handshake between the host(PC) and the target (DSP).
; The host writes a command to CH A. This generates an INT1 on the target.
; The AXST bit on HCR is set to 1.The bit in IFR is polled if it is set
; then it is cleared to clear pending interrupts. The FIFO is cleared
; by reading from the FIFO. The command from host is read thru CH A and
; ARST on TCR is cleared. Another command from target is written to CH A,
; which sets AXST. Also sets XF low. The host polls XF line. The host reads
; CH A which clears ARST on host side and AXST on target side.
;

;=====
;
;-----
;   5.1 serial_init
;
;   5.2 Functional Description
;       This routine initializes the serial port 1 of 541. The serial port is put
;       in reset by writting 0's to RRST and XRST bits and pulled out of reset by
;       writting 1's to both RRST and XRST bits. This routine also puts the AC01
;       in reset and after 12 cycles the AC01 is pulled out of reset. The serial
;       port initialization is done during the 12 cylce latency of the AC01 init.
;-----

;Bit      Name      Function
;0      Reserved    Always read as 0
;1      DLB         Digital loop back: 0 -> Disabled, 1_.Enabled
;2      FO          Format bit: 0 -> data transfered as 8 bit bytes, 1 -> 16 bit
words
;3      FSM         Frame sync pulse: 0 -> serial port in continuous mode, 1 -> FSM
is required
;4      MCM         Clock mode bit: 0 -> CLKX obtained from CLKX pin 1 -> CLKX
obtained from CLKX
;5      TXM         Transmit mode bit: 0 -> Frame sync pulses generated externally
and supplied on FSX pin, 1 -> Internally generated frame sync
pulses out on FSX pin
;6      XRST        Transmit reset bit: 0 -> reset the serial port, 1 -> bring
serial port out of reset
;7      RRS        Receive reset bit: 0 -> reset the serial port, 1 -> bring
serial port out of reset
;8      IN0         Read-only bit reflecting the state of the CLKR pin
;9      IN1         Read-only bit reflecting the state of the CLKX pin
;10     RRDY        Transition from 0 to 1 indicates data is ready to be read
;11     XRDY        Transition from 0 to 1 indicates data is ready to be sent

```

**Example 10–7. Initialization of Serial Port 1 (Continued)**

```

;12  XSREMPY      Transmit shift register empty ( Read-only) 0 -> transitter
                        has experienced underflow
;13  RSRFUL       Receive shift register full flag (Read-only): 0 -> Receiver
                        has experienced overrun
;14  SOFT         Soft bit - 0 -> immdeiate stop, 1-> stop after word completion
;15  FREE         Free run bit: 0 -> behaviour depends on SOFT bit, 1-> free run
                        regardless of SOFT bit
; The system has the following configuration:
;   Uses 16-bit data => FO = 0
;   Operates in burst mode => FSM = 1
;   CLKX is derived from CLKX pin => MCM = 0
;   Frame sync pulses are generated externally by the AIC => TXM = 0
; Therefore, to reset the serial port, the SPC field would have

*****
* This file includes the AC01 registers initialization
* All registers have 2 control bits that initiates serial communication
* There are 2 communication modes - primary and secondary communications
* During primary communication the control bits D00 and D01 are 11 to request
* for a secondary communication. In the secondary serial communications the
* control bits D15 and D14 perform same control function as primary.
* The R/W~ bit at reset is set to 0 placing the device in write mode.

i-----
i   5.1 wrt_cnfg
i
i   5.2 Functional Description
i       Writes new configuration data into the AC01. Assuming a system
i       which processes speech signals and * requires the following parameters
i       Low pass filter cut-off frequency = 3.6 kHz
i       Sampling rate = 8000 Hz
i       Assume the Master clock MCLK = 10.368 MHz
i       This example demonstrates how to program these parameters -
i       the registers affected are:
i       Register A which determines the division of the MCLK frequency
i       to generate the internal filter clock FCLK.
i       It also determines the -3 dB corner frequency of the low-pass filter
i       Register B which determines the division of FCLK to generate
i       the sampling (conversion) frequency

```

**Example 10–9. 'AC01 Register Configuration (Continued)**

```

;           It also determines the -3dB corner frequency of the high-pass filter

; =====
;
; -----
; 5.1 receive_int1
;
; 5.2 Functional Description
; This routine services receive interrupt1. Accumulator A, AR2 and AR3
; are pushed onto the stack since AR2 and AR3 are used in other
; applications. A 512 buffer size of both input and output uses circular
; addressing. After every 256 collection of input samples a flag is set to
; process the data. A PING/PONG buffering scheme is used such that upon
; processing PING buffer, samples are collected in the PONG buffer and vice
; versa.
; -----

```

*Example 10–11. Task Scheduling (Continued)*

```

; 5. SUBROUTINE CODE
;   HeaderBegin
;=====
;
;-----
; 5.1 task_handler
;
; 5.2 Functional Description
; This routine handles the task scheduling. The present_command
; can take values 1,2,3,4,5,6. If
; present_command = 1 - Echo program is enabled
; present_command = 2 - FIR is enabled
; present_command = 3 - IIR is enabled
; present_command = 4 - Symmetric FIR is enabled
; present_command = 5 - Adaptive filter is enabled
; present_command = 6 - FFT is enabled
; For every cycle the program checks if the current task is same
; as previous task if it is, then no initialization is done.
; If its not then circular buffers, variables pointers are intialized
; depending upon the task.
;-----
;
; 5.3 Activation
; Activation example:
; CALL task_handler
; Reentrancy: No
; Recursive : No
;
; 5.4 Inputs
;
; Data structure: present_command
; Data Format: 16-bit variable
; Modified: Yes
; Description: holds the present command
;
; 5.5 Outputs
;
; Data structure: AR6
; Data Format: 16-bit input buffer pointer
; Modified: Yes
; Description: either point to PING/PONG buffer
;
; Data structure: AR7
; Data Format: 16-bit output buffer pointer
; Modified: Yes
; Description: either point to PING/PONG buffer
;
; 5.6 Global
;
; Data structure: last_command
; Data Format: 16-bit variable
; Modified: Yes
; Description: holds the last command

```

*Example 10–11. Task Scheduling (Continued)*

```

;
;   Data structure: d_frame_flag
;   Data Format:    16-bit variable
;   Modified:      Yes
;   Description:   gets reset after 256 samples
;
;   Data structure: d_buffer_count
;   Data Format:    16-bit variable
;   Modified:      Yes
;   Description:   used to load either PING/PONG bfr addresses
;
;   Data structure: input_data
;   Data Format:    16-bit array
;   Modified:      Yes
;   Description:   address of the input data buffer
;
;   Data structure: output_data
;   Data Format:    16-bit array
;   Modified:      Yes
;   Description:   address of the output data buffer
;
;   Data structure: d_input_addr
;   Data Format:    16-bit variable
;   Modified:      Yes
;   Description:   holds either PING/PONG address
;
;   Data structure: d_output_addr
;   Data Format:    16-bit variable

; 5. SUBROUTINE CODE
; HeaderBegin
;=====
;
;-----
; 5.2 sym_fir_init
;
; 5.2.1 Functional Description
; This program uses the FIRS instruction to implement symmetric FIR
; filter. Circular addressing is used for data buffers. The input scheme
; for the data samples is divided into two circular buffers. The first
; buffer contains samples from X(-N/2) to X(-1) and the second buffer
; contains samples from X(-N) to X(-N/2-1).
;-----
;
; 5.2.2 Activation
; Activation example:
; CALL    sym_fir_init
; Reentrancy:    No
; Recursive :    No
;
; 5.2.3 Inputs
;
; Data structure: AR6
; Data Format:    16-bit input buffer pointer
; Modified:      Yes
; Description:    either point to PING/PONG buffer
;
; Data structure: AR4
; Data Format:    16-bit data buffer pointer
; Modified:      Yes
; Description:    uses circular buffer addressing mode to filter
;                 16 tap Low-Pass filter - init. in sym_fir_init
;
; Data structure: AR5
; Data Format:    16-bit coefficient buffer pointer
; Modified:      Yes
; Description:    The 16 tap coeffs comprise the low-pass filter
;                 init. in sym_fir_init

```

; 5.1 adapt_init
;
; 5.1.1 Functional Description
;
;     This subroutine moves filter coefficients from program to data space.
;     Initializes the adaptive coefficients, buffers,vars,and sets the circular
;     buffer address for processing.
; -----

```

*Example 10–16. Adaptive Filtering Using LMS Instruction (Continued)*

; 5. SUBROUTINE CODE
; HeaderBegin
; =====
;
;-----
; 5.2 adapt_task
;
; 5.2.1 Functional Description
;
; This subroutine performs the adaptive filtering.The newest sample is
; stored in a seperate location since filtering and adaptation are performed
; at the same time. Otherwise the oldest sample is over written before
; up dating the w(N-1) coefficient.
;
; d_primary = xh *hcoeff
; d_output = xw *wcoeff

```

**Example 10–16. Adaptive Filtering Using LMS Instruction (Continued)**

```

;   LMS algorithm:
;   w(i+1) = w(i)+d*mu_error*xw(n-i) for i = 0,1,...127 and n = 0,1,.....
;   This program can run in two steps
;   1. Initial stepsize, d_mu = 0x0. At this point, the system is not
;   identified since the coefficients are not adapted and the error
;   signal e (n) is d (n). This is the default mode
;   2. At the EVM debugger command window change the step size
;   d_mu - 0x000, with the command e * d_mu = 0x1000
;   This changes the stepsize. The error signal e(n) in this case
;   is approximately 0 (theoretically) and the system is identified.
;-----;
;   5.2.2 Activation

;
;   5.2 Functional Description
;       This function is called from the main module of the 'C54x Real FFT code.
;       It reorders the original 2N-point real input sequence by using
;       bit-reversed addressing. This new sequence is stored into the data
;       processing buffer of size 2N, where FFT will be performed in-place
;       during Phase Two.
;-----
;
;

;
;   5.2 Functional Description
;   PHASE TWO (LogN)-Stage Complex FFT
;   This function is called from main module of the 'C54x Real FFT code.
;   Here we assume that the original 2N-point real input sequence is al
;   ready packed into an N-point complex sequence and stored into the
;   data processing buffer in bit-reversed order (as done in Phase One).
;   Now we perform an in-place, N-point complex FFT on the data proces
;   sing buffer, dividing the outputs by 2 at the end of each stage to
;   prevent overflow. The resulting N-point complex sequence will be un-
;   packed into a 2N-point complex sequence in Phase Three & Four.
;-----

;
;  5.2 Functional Description
;
;    PHASE THREE & FOUR      Unpacking to 2N Outputs
;    This function is called from the main module of the 'C54x Real FFT
;    code. It first computes four intermediate sequences (RP,RM, IP, IM)
;    from the resulting complex sequence at the end of the previous phase.
;    Next, it uses the four intermediate sequences to form the FFT of the
;    original 2N-point real input. Again, the outputs are divided by 2 to
;    prevent overflow
;-----

i-----
i   5.1 fifo_host_transfer
i
i   5.2 Functional Description
i       This routine transfers a FIFO(64) of data to host thru CH B.
i       In the process, after transferring data from DSP to FIFO sends a com-
i       mand to host thru CH A.The host acknowledges and sends a command to
i       target (DSP) thru CH A. The host transfer can be disabled by setting
i       the K_HOST_FLAG =0
i-----
i

```

**Example 10–22. Data Transfer from FIFO (Continued)**

```

; 5.3 Activation
;   Activation example:
;           CALL    fifo_host_transfer
;
;   Reentrancy:      No
;   Recursive :      No
;
; 5.4 Inputs
;           Data structure: d_output_addr
;           Data Format:   16-bit variable
;           Modified:     NO
;   Description:    holds the starting addr of either PING/PONG addr.
;
;           Data structure: d_fifo_count
;           Data Format:   16-bit var
;           Modified:     Yes
;           Description:  counter for # of transfers
;
;           Data structure: d_fifo_ptr
;           Data Format:   16-bit variable
;           Modified:     Yes
;           Description:  holds the output bffr addr. and incremented by
;           32 for every transfer
;
; 5.5 Outputs
;
;           Data structure: AR7
;           Data Format:   16-bit output buffer pointer
;           Modified:     Yes
;           Description:  either point to PING/PONG buffer
;
; 5.6 Global
;           Data structure: d_command_reg
;           Data Format:   16-bit variable
;           Modified:     Yes
;           Description:  command from host is read thru CH A
;           Data structure: d_command_value
;           Data Format:   16-bit variable
;           Modified:     Yes
;           Description:  holds the command value

;=====
;-----
;  5.1 host_command_int1
;
;  5.2 Functional Description
;      The host generates INT1 DSP whenever it writes to CH A. In INT1
;      service routine, the command from host is read whether the FIFO
;      has been empty. Writes another 32 data from target to FIFO.
;      Sends a command to host. The host acknowledges the command and read
;      the 32 data from the FIFO and sends a command to the target for

```

*Example 10–23. Interrupt 1 Service Routine (Continued)*

```

;         another set of 32 data. This process continues for 6 times till all
;         256 processed samples are transferred to host. Processing INT1 is
;         done background, i.e., INT1 is globally enabled.

# Design Considerations for Using XDS510 Emulator

---

---

---

This appendix assists you in meeting the design requirements of the Texas Instruments XDS510 emulator with respect to IEEE-1149.1 designs and discusses the XDS510 cable (manufacturing part number 2617698-0001). This cable is identified by a label on the cable pod marked *JTAG 3/5V* and supports both standard 3-V and 5-V target system power inputs.

The term *JTAG*, as used in this book, refers to TI scan-based emulation, which is based on the IEEE 1149.1 standard.

For more information concerning the IEEE 1149.1 standard, contact IEEE Customer Service:

### A.1 Designing Your Target System's Emulator Connector (14-Pin Header)

JTAG target devices support emulation through a dedicated emulation port. This port is accessed directly by the emulator and provides emulation functions that are a superset of those specified by IEEE 1149.1. To communicate with the emulator, *your target system must have a 14-pin header* (two rows of seven pins) with the connections that are shown in Figure A–1. Table A–1 describes the emulation signals.

Although you can use other headers, the recommended unshrouded, straight header has these DuPont connector systems part numbers:

- 65610–114
- 65611–114
- 67996–114
- 67997–114

Figure A–1. 14-Pin Header Signals and Header Dimensions

TMS	1	2	$\overline{\text{TRST}}$
TDI	3	4	GND
PD (V <sub>CC</sub> )	5	6	no pin (key) <sup>†</sup>
TDO	7	8	GND
TCK_RET	9	10	GND
TCK	11	12	GND
EMU0	13	14	EMU1

**Header Dimensions:**  
 Pin-to-pin spacing, 0.100 in. (X,Y)  
 Pin width, 0.025-in. square post  
 Pin length, 0.235-in. nominal

<sup>†</sup> While the corresponding female position on the cable connector is plugged to prevent improper connection, the cable lead for pin 6 is present in the cable and is grounded, as shown in the schematics and wiring diagrams in this appendix.

Table A–1. 14-Pin Header Signal Descriptions

Signal	Description	Emulator† State	Target† State
EMU0	Emulation pin 0	I	I/O
EMU1	Emulation pin 1	I	I/O
GND	Ground		
PD(V <sub>CC</sub> )	Presence detect. Indicates that the emulation cable is connected and that the target is powered up. PD should be tied to V <sub>CC</sub> in the target system.	I	O
TCK	Test clock. TCK is a 10.368-MHz clock source from the emulation cable pod. This signal can be used to drive the system test clock.	O	I
TCK_RET	Test clock return. Test clock input to the emulator. May be a buffered or unbuffered version of TCK.	I	O
TDI	Test data input	O	I
TDO	Test data output	I	O
TMS	Test mode select	O	I
$\overline{\text{TRST}}\ddagger$	Test reset	O	I

† I = input; O = output

‡ Do not use pullup resistors on  $\overline{\text{TRST}}$ : it has an internal pulldown device. In a low-noise environment,  $\overline{\text{TRST}}$  can be left floating. In a high-noise environment, an additional pulldown resistor may be needed. (The size of this resistor should be based on electrical current considerations.)

## **A.2 Bus Protocol**

The IEEE 1149.1 specification covers the requirements for the test access port (TAP) bus slave devices and provides certain rules, summarized as follows:

- The TMS and TDI inputs are sampled on the rising edge of the TCK signal of the device.
- The TDO output is clocked from the falling edge of the TCK signal of the device.

When these devices are daisy-chained together, the TDO of one device has approximately a half TCK cycle setup time before the next device's TDI signal. This timing scheme minimizes race conditions that would occur if both TDO and TDI were timed from the same TCK edge. The penalty for this timing scheme is a reduced TCK frequency.

The IEEE 1149.1 specification does not provide rules for bus master (emulator) devices. Instead, it states that the device expects a bus master to provide bus slave compatible timings. The XDS510 provides timings that meet the bus slave rules.

## A.4 Emulator Cable Pod Signal Timing

Figure A–3 shows the signal timings for the emulator cable pod. Table A–2 defines the timing parameters illustrated in the figure. These timing parameters are calculated from values specified in the standard data sheets for the emulator and cable pod and are for reference only. Texas Instruments does not test or guarantee these timings.

The emulator pod uses TCK\_RET as its clock source for internal synchronization. TCK is provided as an optional target system test clock source.

Figure A–3. Emulator Cable Pod Timings

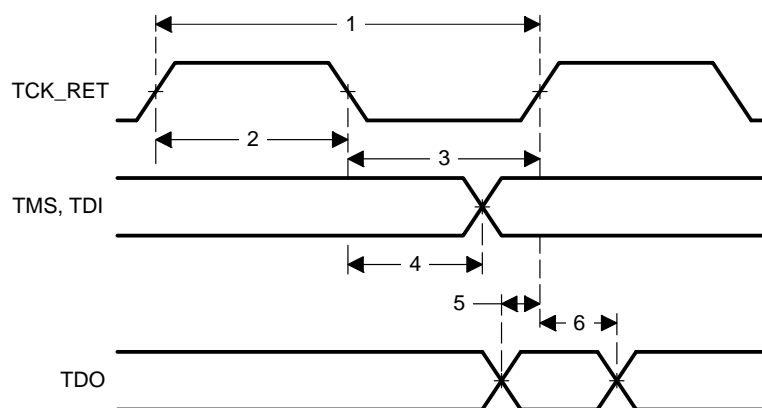

Table A–2. Emulator Cable Pod Timing Parameters

No.	Parameter	Description	Min	Max	Unit
1	$t_c(\text{TCK})$	Cycle time, TCK_RET	35	200	ns
2	$t_w(\text{TCKH})$	Pulse duration, TCK_RET high	15		ns
3	$t_w(\text{TCKL})$	Pulse duration, TCK_RET low	15		ns
4	$t_d(\text{TMS})$	Delay time, TMS or TDI valid for TCK_RET low	6	20	ns
5	$t_{su}(\text{TDO})$	Setup time, TDO to TCK_RET high	3		ns
6	$t_h(\text{TDO})$	Hold time, TDO from TCK_RET high	12		ns

## A.5 Emulation Timing Calculations

Example A–1 and Example A–2 help you calculate emulation timings in your system. For actual target timing parameters, see the appropriate data sheet for the device you are emulating.

The examples use the following assumptions:

$t_{su}(TTMS)$	Setup time, target TMS or TDI to TCK high	10 ns
$t_d(TTDO)$	Delay time, target TDO from TCK low	15 ns
$t_d(bufmax)$	Delay time, target buffer maximum	10 ns
$t_d(bufmin)$	Delay time, target buffer minimum	1 ns
$t_{bufskew}$	Skew time, target buffer between two devices in the same package: $[t_d(bufmax) - t_d(bufmin)] \times 0.15$	1.35 ns
$t_{TCKfactor}$	Duty cycle, assume a 40/60% duty cycle clock	0.4 (40%)

Also, the examples use the following values from Table A–2 on page A-6:

$t_d(TMSmax)$	Delay time, emulator TMS or TDI from TCK_RET low, maximum	20 ns
$t_{su}(TDOmin)$	Setup time, TDO to emulator TCK_RET high, minimum	3 ns

There are two key timing paths to consider in the emulation design:

- The TCK\_RET-to-TMS or TDI path, called  $t_{pd}(TCK\_RET-TMS/TDI)$  (propagation delay time)
- The TCK\_RET-to-TDO path, called  $t_{pd}(TCK\_RET-TDO)$

In the examples, the worst-case path delay is calculated to determine the maximum system test clock frequency.

*Example A–1. Key Timing for a Single-Processor System Without Buffers*

$$\begin{aligned}
 t_{pd(TCK\_RET-TMS/TDI)} &= \frac{[t_{d(TMSmax)} + t_{su(TTMS)}]}{t_{TCKfactor}} \\
 &= \frac{(20 \text{ ns} + 10 \text{ ns})}{0.4} \\
 &= 75 \text{ ns, or } 13.3 \text{ MHz} \\
 t_{pd(TCK\_RET-TDO)} &= \frac{[t_{d(TTDO)} + t_{su(TDOmin)}]}{t_{TCKfactor}} \\
 &= \frac{(15 \text{ ns} + 3 \text{ ns})}{0.4} \\
 &= 45 \text{ ns, or } 22.2 \text{ MHz}
 \end{aligned}$$

In this case, because the TCK\_RET-to-TMS/TDI path requires more time to complete, it is the limiting factor.

*Example A–2. Key Timing for a Single- or Multiple-Processor System With Buffered Input and Output*

$$\begin{aligned}
 t_{pd(TCK\_RET-TMS/TDI)} &= \frac{[t_{d(TMSmax)} + t_{su(TTMS)} + t_{bufskew}]}{t_{TCKfactor}} \\
 &= \frac{(20 \text{ ns} + 10 \text{ ns} + 1.35 \text{ ns})}{0.4} \\
 &= 78.4 \text{ ns, or } 12.7 \text{ MHz} \\
 t_{pd(TCK\_RET-TDO)} &= \frac{[t_{d(TTDO)} + t_{su(TDOmin)} + t_{d(bufmax)}]}{t_{TCKfactor}} \\
 &= \frac{(15 \text{ ns} + 3 \text{ ns} + 10 \text{ ns})}{0.4} \\
 &= 70 \text{ ns, or } 14.3 \text{ MHz}
 \end{aligned}$$

In this case also, because the TCK\_RET-to-TMS/TDI path requires more time to complete, it is the limiting factor.

In a multiprocessor application, it is necessary to ensure that the EMU0 and EMU1 lines can go from a logic low level to a logic high level in less than 10  $\mu$ s, this parameter is called rise time,  $t_r$ . This can be calculated as follows:

$$\begin{aligned}t_r &= 5(R_{\text{pullup}} \times N_{\text{devices}} \times C_{\text{load\_per\_device}}) \\&= 5(4.7 \text{ k}\Omega \times 16 \times 15 \text{ pF}) \\&= 5(4.7 \times 10^3 \Omega \times 16 \times 15 \times 10^{-12} \text{ F}) \\&= 5(1128 \times 10^{-9}) \\&= 5.64 \mu\text{s}\end{aligned}$$

## A.6 Connections Between the Emulator and the Target System

It is extremely important to provide high-quality signals between the emulator and the JTAG target system. You must supply the correct signal buffering, test clock inputs, and multiple processor interconnections to ensure proper emulator and target system operation.

Signals applied to the EMU0 and EMU1 pins on the JTAG target device can be either input or output. In general, these two pins are used as both input and output in multiprocessor systems to handle global run/stop operations. EMU0 and EMU1 signals are applied only as inputs to the XDS510 emulator header.

### A.6.1 Buffering Signals

If the distance between the emulation header and the JTAG target device is greater than 6 inches, the emulation signals must be buffered. If the distance is less than 6 inches, no buffering is necessary. Figure A–4 shows the simpler, no-buffering situation.

The distance between the header and the JTAG target device must be no more than 6 inches. The EMU0 and EMU1 signals must have pullup resistors connected to  $V_{CC}$  to provide a signal rise time of less than 10  $\mu$ s. A 4.7-k $\Omega$  resistor is suggested for most applications.

Figure A–4. Emulator Connections Without Signal Buffering

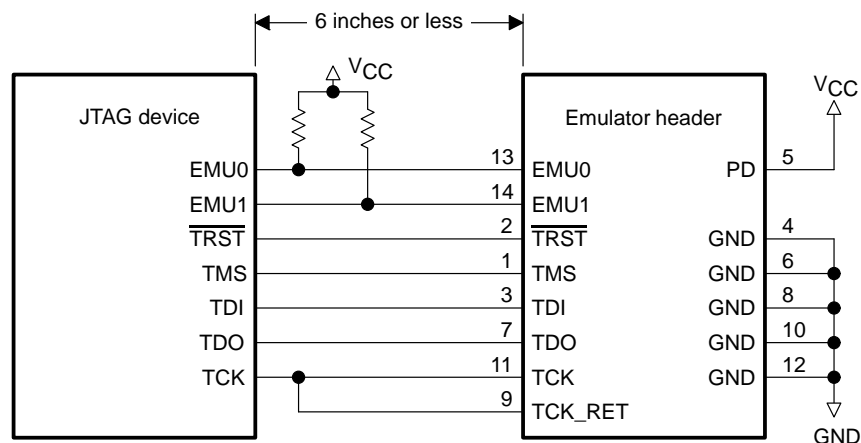

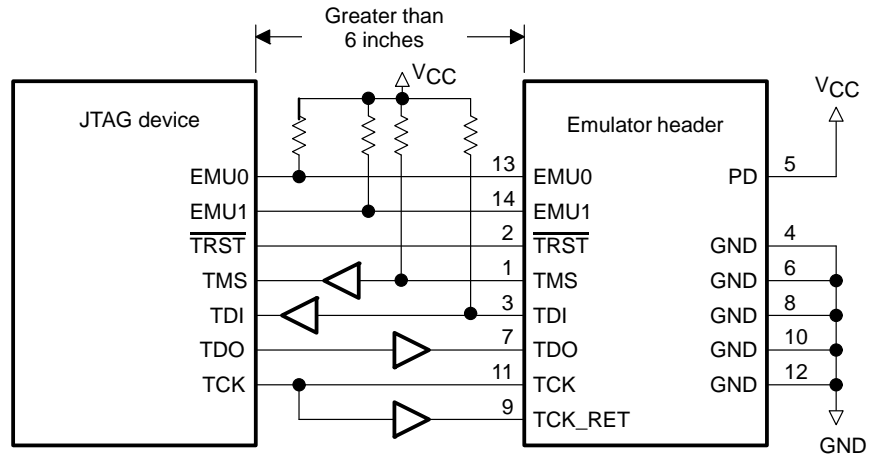

Figure A–5 shows the connections necessary for buffered transmission signals. The distance between the emulation header and the processor is greater than 6 inches. Emulation signals TMS, TDI, TDO, and TCK\_RET are buffered through the same device package.

Figure A–5. Emulator Connections With Signal Buffering

The EMU0 and EMU1 signals must have pullup resistors connected to  $V_{CC}$  to provide a signal rise time of less than 10  $\mu\text{s}$ . A 4.7-k $\Omega$  resistor is suggested for most applications.

The input buffers for TMS and TDI should have pullup resistors connected to  $V_{CC}$  to hold these signals at a known value when the emulator is not connected. A resistor value of 4.7 k $\Omega$  or greater is suggested.

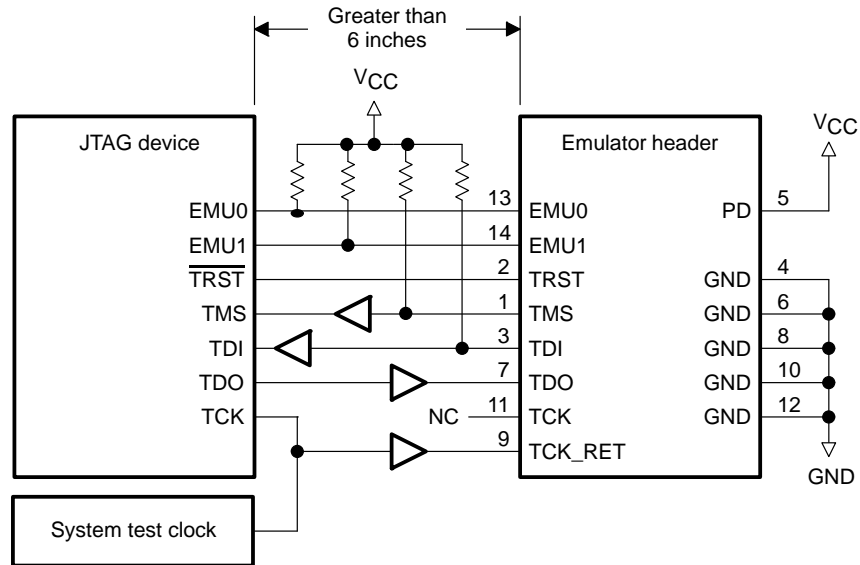

To have high-quality signals (especially the processor TCK and the emulator TCK\_RET signals), you may have to employ special care when routing the printed wiring board trace. You also may have to use termination resistors to match the trace impedance. The emulator pod provides optional internal parallel terminators on the TCK\_RET and TDO. TMS and TDI provide fixed series termination.

Because  $\overline{\text{TRST}}$  is an asynchronous signal, it should be buffered as needed to ensure sufficient current to all target devices.

### A.6.2 Using a Target-System Clock

Figure A–6 shows an application with the system test clock generated in the target system. In this application, the emulator’s TCK signal is left unconnected.

Figure A–6. Target-System-Generated Test Clock

**Note:** When the TMS and TDI lines are buffered, pullup resistors must be used to hold the buffer inputs at a known level when the emulator cable is not connected.

There are two benefits in generating the test clock in the target system:

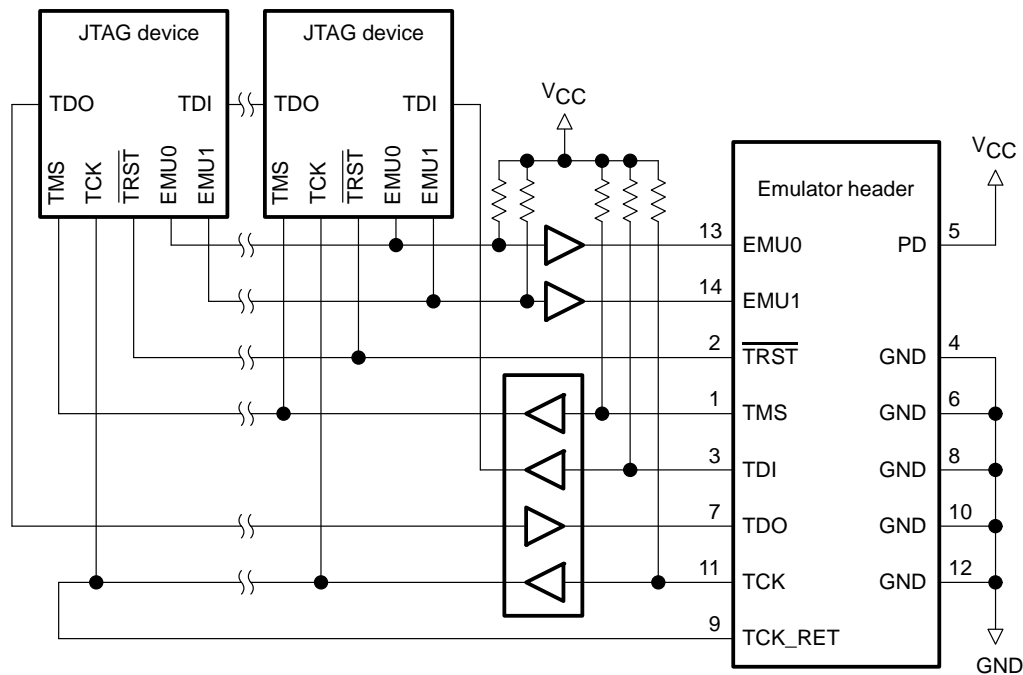

- The emulator provides only a single 10.368-MHz test clock. If you allow the target system to generate your test clock, you can set the frequency to match your system requirements.
- In some cases, you may have other devices in your system that require a test clock when the emulator is not connected. The system test clock also serves this purpose.

### A.6.3 Configuring Multiple Processors

Figure A–7 shows a typical daisy-chained multiprocessor configuration that meets the minimum requirements of the IEEE 1149.1 specification. The emulation signals are buffered to isolate the processors from the emulator and provide adequate signal drive for the target system. One of the benefits of this interface is that you can slow down the test clock to eliminate timing problems. Follow these guidelines for multiprocessor support:

- The processor TMS, TDI, TDO, and TCK signals must be buffered through the same physical device package for better control of timing skew.
- The input buffers for TMS, TDI, and TCK should have pullup resistors connected to  $V_{CC}$  to hold these signals at a known value when the emulator is not connected. A resistor value of 4.7 k $\Omega$  or greater is suggested.
- Buffering EMU0 and EMU1 is optional but highly recommended to provide isolation. These are not critical signals and do not have to be buffered through the same physical package as TMS, TCK, TDI, and TDO.

Figure A–7. Multiprocessor Connections

## A.7 Physical Dimensions for the 14-Pin Emulator Connector

The JTAG emulator target cable consists of a 3-foot section of jacketed cable that connects to the emulator, an active cable pod, and a short section of jacketed cable that connects to the target system. The overall cable length is approximately 3 feet 10 inches. Figure A–8 and Figure A–9 (page A-15) show the physical dimensions for the target cable pod and short cable. The cable pod box is nonconductive plastic with four recessed metal screws.

Figure A–8. Pod/Connector Dimensions

**Note:** All dimensions are in inches and are nominal dimensions, unless otherwise specified. Pin-to-pin spacing on the connector is 0.100 inches in both the X and Y planes.

*Figure A-9. 14-Pin Connector Dimensions*

## A.8 Emulation Design Considerations

This section describes the use and application of the scan path linker (SPL), which can simultaneously add all four secondary JTAG scan paths to the main scan path. It also describes the use of the emulation pins and the configuration of multiple processors.

### A.8.1 Using Scan Path Linkers

You can use the TI ACT8997 scan path linker (SPL) to divide the JTAG emulation scan path into smaller, logically connected groups of 4 to 16 devices. As described in the *Advanced Logic and Bus Interface Logic Data Book*, the SPL is compatible with the JTAG emulation scanning. The SPL is capable of adding any combination of its four secondary scan paths into the main scan path.

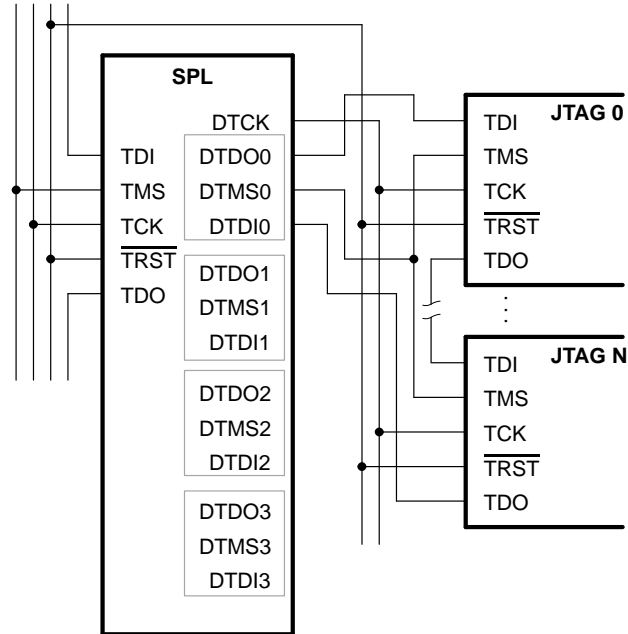

A system of multiple, secondary JTAG scan paths has better fault tolerance and isolation than a single scan path. Since an SPL has the capability of adding all secondary scan paths to the main scan path simultaneously, it can support global emulation operations, such as starting or stopping a selected group of processors.

TI emulators do not support the nesting of SPLs (for example, an SPL connected to the secondary scan path of another SPL). However, you can have multiple SPLs on the main scan path.

Scan path selectors are not supported by this emulation system. The TI ACT8999 scan path selector is similar to the SPL, but it can add only one of its secondary scan paths at a time to the main JTAG scan path. Thus, global emulation operations are not assured with the scan path selector.

You can insert an SPL on a backplane so that you can add up to four device boards to the system without the jumper wiring required with nonbackplane devices. You connect an SPL to the main JTAG scan path in the same way you connect any other device. Figure A–10 shows how to connect a secondary scan path to an SPL.

Figure A–10. Connecting a Secondary JTAG Scan Path to a Scan Path Linker

The  $\overline{\text{TRST}}$  signal from the main scan path drives all devices, even those on the secondary scan paths of the SPL. The TCK signal on each target device on the secondary scan path of an SPL is driven by the SPL's DTCK signal. The TMS signal on each device on the secondary scan path is driven by the respective DTMS signals on the SPL.

DTDO0 on the SPL is connected to the TDI signal of the first device on the secondary scan path. DTDI0 on the SPL is connected to the TDO signal of the last device in the secondary scan path. Within each secondary scan path, the TDI signal of a device is connected to the TDO signal of the device before it. If the SPL is on a backplane, its secondary JTAG scan paths are on add-on boards; if signal degradation is a problem, you may need to buffer both the  $\overline{\text{TRST}}$  and DTCK signals. Although degradation is less likely for DTMS $_n$  signals, you may also need to buffer them for the same reasons.

**A.8.2 Emulation Timing Calculations for a Scan Path Linker (SPL)**

Example A–3 and Example A–4 help you to calculate the key emulation timings in the SPL secondary scan path of your system. For actual target timing parameters, see the appropriate device data sheet for your target device.

The examples use the following assumptions:

$t_{su}(TTMS)$	Setup time, target TMS/TDI to TCK high	10 ns
$t_d(TTDO)$	Delay time, target TDO from TCK low	15 ns
$t_d(bufmax)$	Delay time, target buffer, maximum	10 ns
$t_d(bufmin)$	Delay time, target buffer, minimum	1 ns
$t_{(bufskew)}$	Skew time, target buffer, between two devices in the same package: $[t_d(bufmax) - t_d(bufmin)] \times 0.15$	1.35 ns
$t_{(TCKfactor)}$	Duty cycle, TCK assume a 40/60% clock	0.4 (40%)

Also, the examples use the following values from the SPL data sheet:

$t_d(DTMSmax)$	Delay time, SPL DTMS/DTDO from TCK low, maximum	31 ns
$t_{su}(DTDLmin)$	Setup time, DTDI to SPL TCK high, minimum	7 ns
$t_d(DTCKHmin)$	Delay time, SPL DTCK from TCK high, minimum	2 ns
$t_d(DTCKLmax)$	Delay time, SPL DTCK from TCK low, maximum	16 ns

There are two key timing paths to consider in the emulation design:

- The TCK-to-DTMS/DTDO path, called  $t_{pd}(TCK-DTMS)$
- The TCK-to-DTDI path, called  $t_{pd}(TCK-DTDI)$

Of the following two cases, the worst-case path delay is calculated to determine the maximum system test clock frequency.

*Example A–3. Key Timing for a Single-Processor System Without Buffering (SPL)*

$$\begin{aligned}
 t_{pd(TCK-DTMS)} &= \frac{\left[ t_{d(DTMSmax)} + t_{d(DTCKHmin)} + t_{su(TTMS)} \right]}{t_{TCKfactor}} \\
 &= \frac{(31 \text{ ns} + 2 \text{ ns} + 10 \text{ ns})}{0.4} \\
 &= 107.5 \text{ ns, or } 9.3 \text{ MHz} \\
 t_{pd(TCK-DTDI)} &= \frac{\left[ t_{d(TTDO)} + t_{d(DTCKLmax)} + t_{su(DTDLmin)} \right]}{t_{TCKfactor}} \\
 &= \frac{(15 \text{ ns} + 16 \text{ ns} + 7 \text{ ns})}{0.4} \\
 &= 9.5 \text{ ns, or } 10.5 \text{ MHz}
 \end{aligned}$$

In this case, the TCK-to-DTMS/DTDl path is the limiting factor.

*Example A–4. Key Timing for a Single- or Multiprocessor-System With Buffered Input and Output (SPL)*

$$\begin{aligned}
 t_{pd(TCK-TDMS)} &= \frac{\left[ t_{d(DTMSmax)} + t_{d(DTCKHmin)} + t_{su(TTMS)} + t_{(bufskew)} \right]}{t_{TCKfactor}} \\
 &= \frac{(31 \text{ ns} + 2 \text{ ns} + 10 \text{ ns} + 1.35 \text{ ns})}{0.4} \\
 &= 110.9 \text{ ns, or } 9.0 \text{ MHz} \\
 t_{pd(TCK-DTDI)} &= \frac{\left[ t_{d(TTDO)} + t_{d(DTCKLmax)} + t_{su(DTDLmin)} + t_{d(bufskew)} \right]}{t_{TCKfactor}} \\
 &= \frac{(15 \text{ ns} + 15 \text{ ns} + 7 \text{ ns} + 10 \text{ ns})}{0.4} \\
 &= 120 \text{ ns, or } 8.3 \text{ MHz}
 \end{aligned}$$

In this case, the TCK-to-DTDI path is the limiting factor.

### A.8.3 Using Emulation Pins

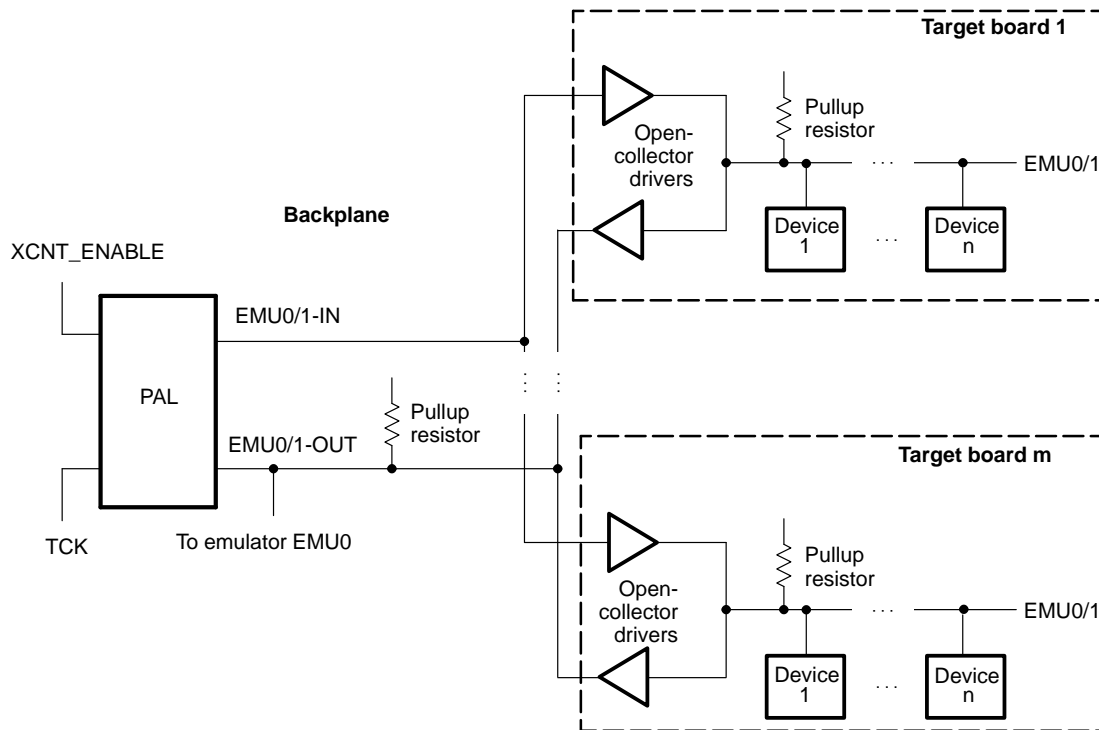

The EMU0/1 pins of TI devices are bidirectional, 3-state output pins. When in an inactive state, these pins are at high impedance. When the pins are active, they provide one of two types of output:

- ❑ **Signal Event.** The EMU0/1 pins can be configured via software to signal internal events. In this mode, driving one of these pins low can cause devices to signal such events. To enable this operation, the EMU0/1 pins function as open-collector sources. External devices such as logic analyzers can also be connected to the EMU0/1 signals in this manner. If such an external source is used, it must also be connected via an open-collector source.
- ❑ **External Count.** The EMU0/1 pins can be configured via software as totem-pole outputs for driving an external counter. If the output of more than one device is configured for totem-pole operation, then these devices can be damaged. The emulation software detects and prevents this condition. However, the emulation software has no control over external sources on the EMU0/1 signal. Therefore, all external sources must be inactive when any device is in the external count mode.

TI devices can be configured by software to halt processing if their EMU0/1 pins are driven low. This feature combined with the signal event output, allows one TI device to halt all other TI devices on a given event for system-level debugging.

If you route the EMU0/1 signals between multiple boards, they require special handling because they are more complex than normal emulation signals. Figure A–11 shows an example configuration that allows any processor in the system to stop any other processor in the system. Do not tie the EMU0/1 pins of more than 16 processors together in a single group without using buffers. Buffers provide the crisp signals that are required during a RUNB (run benchmark) debugger command or when the external analysis counter feature is used.

Figure A–11. EMU0/1 Configuration to Meet Timing Requirements of Less Than 25 ns

- Notes:**
- 1) The low time on EMU0/1-IN should be at least one TCK cycle and less than 10  $\mu$ s. Software sets the EMU0/1-OUT pin to a high state.
  - 2) To enable the open-collector driver and pullup resistor on EMU1 to provide rise/fall times of less than 25 ns, the modification shown in this figure is suggested. Rise times of more than 25 ns can cause the emulator to detect false edges during the RUNB command or when the external counter selected from the debugger analysis menu is used.

These seven important points apply to the circuitry shown in Figure A–11 and the timing shown in Figure A–12:

- Open-collector drivers isolate each board. The EMU0/1 pins are tied together on each board.
- At the board edge, the EMU0/1 signals are split to provide both input and output connections. This is required to prevent the open-collector drivers from acting as latches that can be set only once.
- The EMU0/1 signals are bused down the backplane. Pullup resistors must be installed as required.

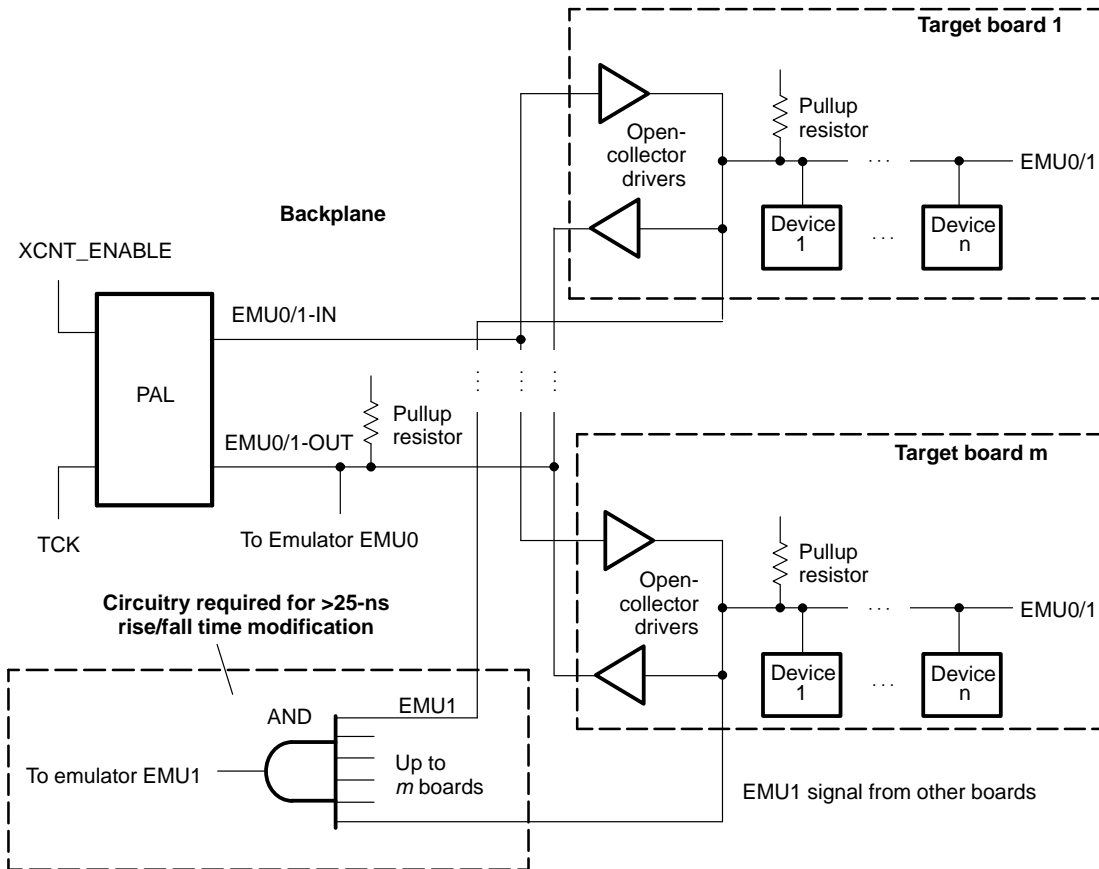

- ❑ The bused EMU0/1 signals go into a programmable logic array device PAL<sup>®</sup> whose function is to generate a low pulse on the EMU0/1-IN signal when a low level is detected on the EMU0/1-OUT signal. This pulse must be longer than one TCK period to affect the devices but less than 10  $\mu$ s to avoid possible conflicts or retriggering once the emulation software clears the device's pins.
- ❑ During a RUNB debugger command or other external analysis count, the EMU0/1 pins on the target device become totem-pole outputs. The EMU1 pin is a ripple carry-out of the internal counter. EMU0 becomes a *processor-halted* signal. During a RUNB or other external analysis count, the EMU0/1-IN signal to all boards must remain in the high (disabled) state. You must provide some type of external input (XCNT\_ENABLE) to the PAL<sup>®</sup> to disable the PAL<sup>®</sup> from driving EMU0/1-IN to a low state.
- ❑ If you use sources other than TI processors (such as logic analyzers) to drive EMU0/1, their signal lines must be isolated by open-collector drivers and be inactive during RUNB and other external analysis counts.
- ❑ You must connect the EMU0/1-OUT signals to the emulation header or directly to a test bus controller.

Figure A–12. Suggested Timings for the EMU0 and EMU1 Signals

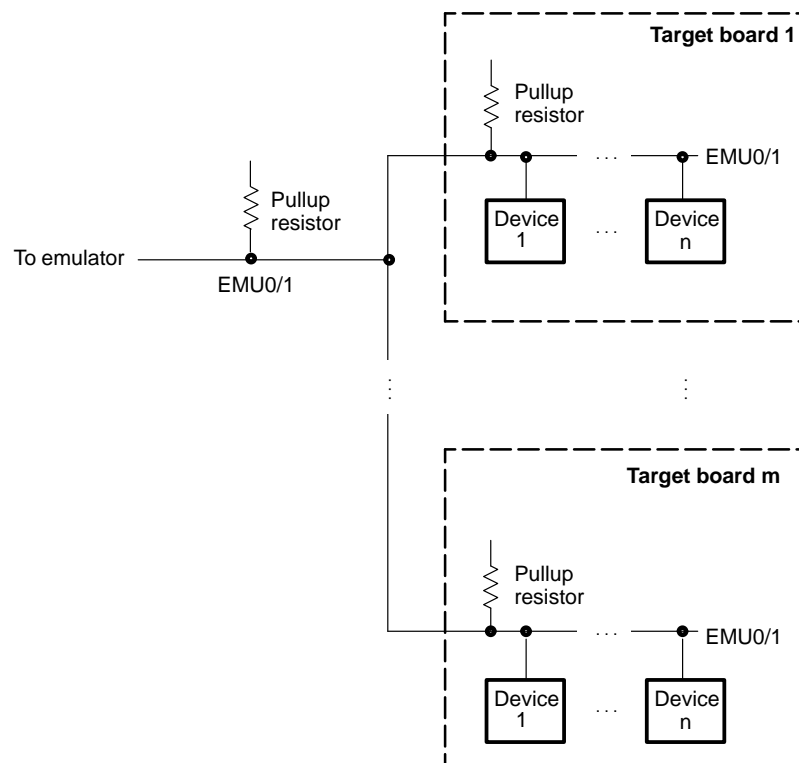

*Figure A–13. EMU0/1 Configuration With Additional AND Gate to Meet Timing Requirements of Greater Than 25 ns*

- Notes:**
- 1) The low time on EMU0/1-IN should be at least one TCK cycle and less than 10  $\mu$ s. Software will set the EMU0/1-OUT port to a high state.
  - 2) To enable the open-collector driver and pullup resistor on EMU1 to provide rise/fall time of greater than 25 ns, the modification shown in this figure is suggested. Rise times of more than 25 ns can cause the emulator to detect false edges during the RUNB command or when the external counter selected from the debugger analysis menu is used.

You do not need to have devices on one target board stop devices on another target board using the EMU0/1 signals (see the circuit in Figure A–14). In this configuration, the global-stop capability is lost. It is important not to overload EMU0/1 with more than 16 devices.

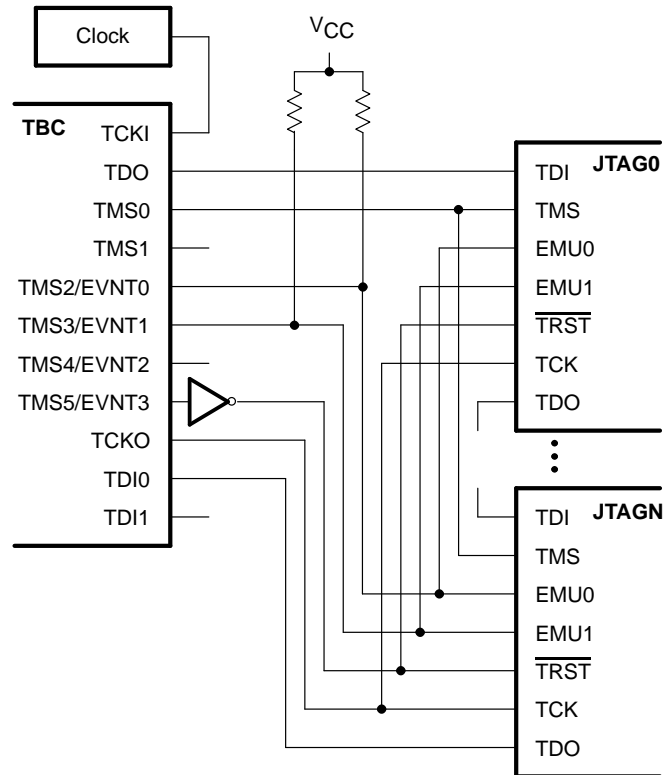

Figure A–14. EMU0/1 Configuration Without Global Stop

**Note:** The open-collector driver and pullup resistor on EMU1 must be able to provide rise/fall times of less than 25 ns. Rise times of more than 25 ns can cause the emulator to detect false edges during the RUNB command or when the external counter selected from the debugger analysis menu is used. If this condition cannot be met, then the EMU0/1 signals from the individual boards must be ANDed together (as shown in Figure A–14) to produce an EMU0/1 signal for the emulator.

#### A.8.4 Performing Diagnostic Applications

For systems that require built-in diagnostics, it is possible to connect the emulation scan path directly to a TI ACT8990 test bus controller (TBC) instead of the emulation header. The TBC is described in the Texas Instruments *Advanced Logic and Bus Interface Logic Data Book*. Figure A–15 shows the scan path connections of  $n$  devices to the TBC.

Figure A–15. TBC Emulation Connections for *n* JTAG Scan Paths

In the system design shown in Figure A–15, the TBC emulation signals TCKI, TDO, TMS0, TMS2/EVNT0, TMS3/EVNT1, TMS5/EVNT3, TCKO, and TDI0 are used, and TMS1, TMS4/EVNT2, and TDI1 are not connected. The target devices' EMU0 and EMU1 signals are connected to  $V_{CC}$  through pullup resistors and tied to the TBC's TMS2/EVNT0 and TMS3/EVNT1 pins, respectively. The TBC's TCKI pin is connected to a clock generator. The TCK signal for the main JTAG scan path is driven by the TBC's TCKO pin.

On the TBC, the TMS0 pin drives the TMS pins on each device on the main JTAG scan path. TDO on the TBC connects to TDI on the first device on the main JTAG scan path. TDI0 on the TBC is connected to the TDO signal of the last device on the main JTAG scan path. Within the main JTAG scan path, the TDI signal of a device is connected to the TDO signal of the device before it.  $\overline{\text{TRST}}$  for the devices can be generated either by inverting the TBC's TMS5/EVNT3 signal for software control or by logic on the board itself.

# Development Support and Part Order Information

---

---

---

This appendix provides development support information, device part numbers, and support tool ordering information for the '54x.

Each '54x support product is described in the *TMS320 DSP Development Support Reference Guide*. In addition, more than 100 third-party developers offer products that support the TI TMS320 family. For more information, refer to the *TMS320 Third-Party Support Reference Guide*.

For information on pricing and availability, contact the nearest TI Field Sales Office or authorized distributor. See the list at the back of this book.

<b>Topic</b>	<b>Page</b>
<b>B.1 Development Support</b> .....	<b>B-2</b>
<b>B.2 Part Order Information</b> .....	<b>B-5</b>

## B.1 Development Support

This section describes the development support provided by Texas Instruments.

### B.1.1 Development Tools

TI offers an extensive line of development tools for the '54x generation of DSPs, including tools to evaluate the performance of the processors, generate code, develop algorithm implementations, and fully integrate and debug software and hardware modules.

#### ***Code Generation Tools***

- ❑ The optimizing ANSI C compiler translates ANSI C language directly into highly optimized assembly code. You can then assemble and link this code with the TI assembler/linker, which is shipped with the compiler. This product is currently available for PCs (DOS, DOS extended memory, OS/2), HP workstations, and SPARC workstations. See the *TMS320C54x Optimizing C Compiler User's Guide* for detailed information about this tool.
- ❑ The assembler/linker converts source mnemonics to executable object code. This product is currently available for PCs (DOS, DOS extended memory, OS/2). The '54x assembler for HP and SPARC workstations is available only as part of the optimizing '54x compiler. See the *TMS320C54x Assembly Language Tools User's Guide* for detailed information about available assembly-language tools.

#### ***System Integration and Debug Tools***

- ❑ The simulator simulates (via software) the operation of the '54x and can be used in C and assembly software development. This product is currently available for PCs (DOS, Windows), HP workstations, and SPARC workstations. See the *TMS320C54x C Source Debugger User's Guide* for detailed information about the debugger.
- ❑ The XDS510 emulator performs full-speed in-circuit emulation with the '54x, providing access to all registers as well as to internal and external memory of the device. It can be used in C and assembly software development and has the capability to debug multiple processors. This product is currently available for PCs (DOS, Windows, OS/2), HP workstations, and SPARC workstations. This product includes the emulator board (emulator box, power supply, and SCSI connector cables in the HP and SPARC versions), the '54x C source debugger and the JTAG cable.

Because the 'C2xx, 'C3x, 'C4x, and 'C5x XDS510 emulators also come with the same emulator board (or box) as the '54x, you can buy the '54x C Source Debugger Software as a separate product called the '54x C Source Debugger Conversion Software. This enables you to debug '54x applications with a previously purchased emulator board. The emulator cable that comes with the 'C3x XDS510 emulator cannot be used with the '54x. You need the JTAG emulation conversion cable (see Section B.2) instead. The emulator cable that comes with the 'C5x XDS510 emulator can be used with the '54x without any restriction. See the *TMS320C54x C Source Debugger User's Guide*) for detailed information about the '54x emulator.

- The TMS320C54x evaluation module (EVM) is a PC/AT plug-in card that lets you evaluate certain characteristics of the '54x digital signal processor to see if it meets your application requirements. The '54x EVM carries a '541 DSP on board to allow full-speed verification of '54x code. The EVM has 5K bytes of on-chip program/data RAM, 28K bytes of on-chip ROM, two serial ports, a timer, access to 64K bytes each of external program and data RAM, and an external analog interface for evaluation of the '54x family of devices for applications. See the *TMS320C54x Evaluation Module Technical Reference* for detailed information about the '54x EVM.

### B.1.2 Third-Party Support

The TMS320 family is supported by products and services from more than 100 independent third-party vendors and consultants. These support products take various forms (both as software and hardware), from cross-assemblers, simulators, and DSP utility packages to logic analyzers and emulators. The expertise of those involved in support services ranges from speech encoding and vector quantization to software/hardware design and system analysis.

To ask about third-party services, products, applications, and algorithm development packages, contact the third party directly. Refer to the *TMS320 Third-Party Support Reference Guide* for addresses and phone numbers.

### **B.1.3 Technical Training Organization (TTO) TMS320 Workshops**

**'54x DSP Design Workshop.** This workshop is tailored for hardware and software design engineers and decision-makers who will be designing and utilizing the '54x generation of DSP devices. Hands-on exercises throughout the course give participants a rapid start in developing '54x design skills. Microprocessor/assembly language experience is required. Experience with digital design techniques and C language programming experience is desirable.

These topics are covered in the '54x workshop:

- '54x architecture/instruction set
- Use of the PC-based software simulator
- Use of the '54x assembler/linker
- C programming environment
- System architecture considerations
- Memory and I/O interfacing
- Development support

For registration information, pricing, or to enroll, call (800)336-5236, ext. 3904.

### **B.1.4 Assistance**

For assistance to TMS320 questions on device problems, development tools, documentation, software upgrades, and new products, you can contact TI. See *If You Need Assistance* in *Preface* for information.

## B.2 Part Order Information

This section describes the part numbers of '54x devices, development support hardware, and software tools.

### B.2.1 Device and Development Support Tool Nomenclature Prefixes

To designate the stages in the product development cycle, TI assigns prefixes to the part numbers of all TMS320 devices and support tools. Each TMS320 device has one of three prefix designators: TMX, TMP, or TMS. Each support tool has one of two possible prefix designators: TMDX or TMDS. These prefixes represent evolutionary stages of product development from engineering prototypes (TMX/TMDX) through fully qualified production devices and tools (TMS/TMDS). This development flow is defined below.

#### Device Development Evolutionary Flow:

- TMX** The part is an experimental device that is not necessarily representative of the final device's electrical specifications.
- TMP** The part is a device from a final silicon die that conforms to the device's electrical specifications but has not completed quality and reliability verification.
- TMS** The part is a fully qualified production device.

#### Support Tool Development Evolutionary Flow:

- TMDX** The development-support product that has not yet completed Texas Instruments internal qualification testing.
- TMDS** The development-support product is a fully qualified development support product.

TMX and TMP devices and TMDX development support tools are shipped with the following disclaimer:

"Developmental product is intended for internal evaluation purposes."

TMS devices and TMDS development support tools have been fully characterized, and the quality and reliability of the device has been fully demonstrated. Texas Instruments standard warranty applies to these products.

---

**Note:**

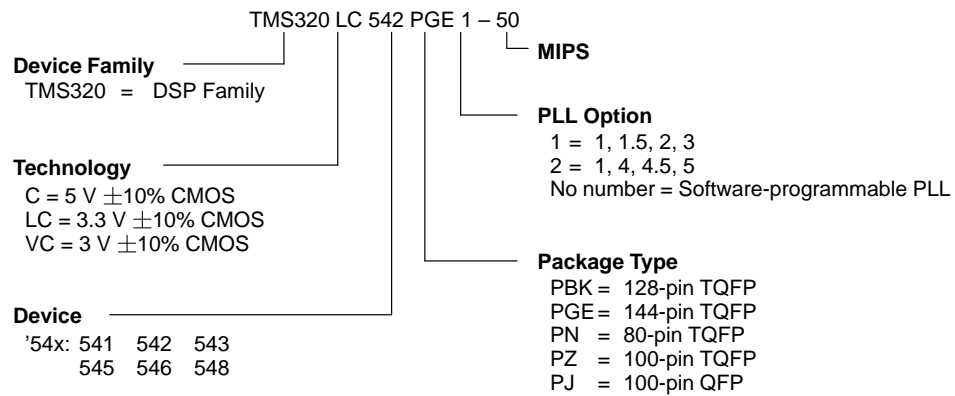

It is expected that prototype devices (TMX or TMP) have a greater failure rate than standard production devices. Texas Instruments recommends that these devices *not* be used in any production system, because their expected end-use failure rate is still undefined. Only qualified production devices should be used.

---

**B.2.2 Device Nomenclature**

TI device nomenclature includes the device family name and a suffix. Figure B–1 provides a legend for reading the complete device name for any '54x device family member.

Figure B–1. TMS320C54x Device Nomenclature

### B.2.3 Development Support Tools

Table B–1 lists the development support tools available for the '54x, the platform on which they run, and their part numbers.

Table B–1. Development Support Tools Part Numbers

Development Tool	Platform	Part Number
Assembler/Linker	PC (DOS™)	TMDS324L850-02
C Compiler/Assembler/Linker	PC (DOS™, Windows™, OS/2™)	TMDS324L855-02
C Compiler/Assembler/Linker	HP (HP-UX™) / SPARC™ (Sun OS™)	TMDS324L555-08
C Source Debugger Conversion Software	PC (DOS™, Windows™, OS/2™) (XDS510™)	TMDS32401L0
C Source Debugger Conversion Software	HP (HP-UX™) / SPARC™ (Sun OS™) (XDS510WS™)	TMDS32406L0
Evaluation Module (EVM)	PC (DOS™, Windows™, OS/2™)	TMDX3260051
Simulator (C language)	PC (DOS™, Windows™)	TMDS324L851-02
Simulator (C language)	HP (HP-UX™) / SPARC™ (Sun OS™)	TMDS324L551-09
XDS510 Emulator†	PC (DOS™, Windows™, OS/2™)	TMDS00510
XDS510WS Emulator‡	HP (HP-UX™) / SPARC™ (Sun OS™) (SCSI)	TMDS00510WS
3 V/5 V PC/SPARC JTAG Emulation Cable	XDS510™ / XDS510WS™	TMDS3080002

† Includes XDS510 board and JTAG cable; TMDS32401L0 C-source debugger conversion software not included

‡ Includes XDS510WS box, SCSI cable, power supply, and JTAG cable; TMDS32406L0 C-source debugger conversion software not included

## A

**A:** See *accumulator A*.

**accumulator:** A register that stores the results of an operation and provides an input for subsequent arithmetic logic unit (ALU) operations.

**accumulator A:** 40-bit register that stores the result of an operation and provides an input for subsequent arithmetic logic unit (ALU) operations.

**accumulator B:** 40-bit registers that stores the result of an operation and provides an input for subsequent arithmetic logic unit (ALU) operations.

**adder:** A unit that adds or subtracts two numbers.

**address:** The location of a word in memory.

**address bus:** A group of connections used to route addresses. The '54x has four 16-bit address busses: CAB, DAB, EAB, and PAB.

**addressing mode:** The method by which an instruction calculates the location of an object in memory.

**address visibility mode bit (AVIS):** A bit in processor mode status register (PMST) that determines whether or not the internal program address appears on the device's external address bus pins.

**ALU:** *arithmetic logic unit*. The part of the CPU that performs arithmetic and logic operations.

**analog-to-digital (A/D) converter:** Circuitry that translates an analog signal to a digital signal.

**AR0–AR7:** *auxiliary registers 0–7*. Eight 16-bit registers that can be accessed by the CPU and modified by the auxiliary register arithmetic units (ARAUs) and are used primarily for data memory addressing.

**ARAU:** See *auxiliary register arithmetic unit*.

**ARP:** See *auxiliary register pointer*.

**ASM:** See *accumulator shift mode field*.

**auxiliary register arithmetic unit:** An unsigned, 16-bit arithmetic logic unit (ALU) used to calculate indirect addresses using auxiliary registers.

**auxiliary register file:** The area in data memory containing the eight 16-bit auxiliary registers. See also *auxiliary registers*.

**auxiliary register pointer (ARP):** A 3-bit field in status register 0 (ST0) used as a pointer to the currently-selected auxiliary register, when the device is operating in 'C5x/'C2xx compatibility mode.

**auxiliary registers:** Eight 16-bit registers (AR7 – AR0) that are used as pointers to an address within data space. These registers are operated on by the auxiliary register arithmetic units (ARAUs) and are selected by the auxiliary register pointer (ARP). See also *auxiliary register arithmetic unit*.

**AVIS:** See *address visibility mode bit*.

## B

**B:** See *accumulator B*.

**bank-switching control register (BSCR):** A 16-bit register that defines the external memory bank size and enables or disables automatic insertion of extra cycles when accesses cross memory bank boundaries.

**barrel shifter:** A unit that rotates bits in a word.

**BK:** See *circular buffer size register*.

**block-repeat active flag (BRAFF):** A bit in status register 1 (ST1) that indicates whether or not a block repeat is currently active.

**block-repeat counter (BRC):** A 16-bit register that specifies the number of times a block of code is to be repeated when a block repeat is performed.

**block-repeat end address register (REA):** A 16-bit memory-mapped register containing the end address of a code segment being repeated.

**block-repeat start address register (RSA):** A 16-bit memory-mapped register containing the start address of a code segment being repeated.

**boot:** The process of loading a program into program memory.

**boot loader:** A built-in segment of code that transfers code from an external source to program memory at power-up.

**BRC:** See *block-repeat counter*.

**BSCR:** See *bank-switching control register*.

**BSP:** *buffered serial port*. An enhanced synchronous serial port that includes an autobuffering unit (ABU) that reduces CPU overhead in performing serial operations.

**BSPCE:** *BSP control extension register*. A 16-bit memory-mapped register that contains status and control bits for the buffered serial port (BSP) interface. The 10 LSBs of the SPCE are dedicated to serial port interface control, whereas the 6 MSBs are used for autobuffering unit (ABU) control.

**butterfly:** A kernel function for computing an N-point fast Fourier transform (FFT), where N is a power of 2. The combinational pattern of inputs resembles butterfly wings.

**C**

**C:** See *carry bit*.

**C16:** A bit in status register 1 (ST1) that determines whether the ALU operates in dual 16-bit mode or in double-precision mode.

**carry bit:** A bit in status register 0 (ST0) used by the ALU in extended arithmetic operations and accumulator shifts and rotates. The carry bit can be tested by conditional instructions.

**circular buffer size register (BK):** A 16-bit register used by the auxiliary register arithmetic units (ARAUs) to specify the data-block size in circular addressing.

**code:** A set of instructions written to perform a task; a computer program or part of a program.

**cold boot:** The process of loading a program into program memory at power-up.

**compare, select, and store unit (CSSU):** An application-specific hardware unit dedicated to add/compare/select operations of the Viterbi operator.

**CSSU:** See *compare, select, and store unit*

**D**

- DAGEN:** See *data-address generation logic (DAGEN)*.
- DARAM:** *dual-access RAM*. Memory that can be read from and written to in the same clock cycle.
- data address bus:** A group of connections used to route data memory addresses. The '54x has three 16-bit buses that carry data memory addresses: *CAB*, *DAB*, and *EAB*.
- data-address generation logic (DAGEN):** Logic circuitry that generates the addresses for data memory reads and writes. See also *program-address generation logic (PAGEN)*.
- data bus:** A group of connections used to route data. The '54x has three 16-bit data buses: *CB*, *DB*, and *EB*.
- data memory:** A memory region used for storing and manipulating data. Addresses 00h–1Fh of data memory contain CPU registers. Addresses 20h–5Fh of data memory contain peripheral registers.
- data page pointer (DP):** A 9-bit field in status register 0 (ST0) that specifies which of 512,  $128 \times 16$  word pages is currently selected for direct address generation. DP provides the nine MSBs of the data-memory address; the *dma* provides the lower seven. See also *dma*.
- data ROM bit (DROM):** A bit in PMST that determines whether or not part of the on-chip ROM is mapped into data space.
- digital-to-analog (D/A) converter:** Circuitry that translates a digital signal to an analog signal.
- direct data-memory address bus:** A 16-bit bus that carries the direct address for data memory.
- direct memory address (dma, DMA) :** The seven LSBs of a direct-addressed instruction that are concatenated with the data page pointer (DP) to generate the entire data memory address. See also *data page pointer*.
- dma:** See *direct memory address*.
- DP:** See *data page pointer*.
- DRB:** *direct data-memory address bus*. A 16-bit bus that carries the direct address for data memory.
- DROM:** See *data ROM bit*.

**E**

**exponent encoder (EXP):** An application-specific hardware device that computes the exponent value of the accumulator.

**external interrupt:** A hardware interrupt triggered by a pin ( $\overline{\text{INT0}}\text{--}\overline{\text{INT3}}$ ).

**F**

**fast Fourier transform (FFT):** An efficient method of computing the discrete Fourier transform, which transforms functions between the time domain and frequency domain. The time-to-frequency domain is called the forward transform, and the frequency-to-time domain is called the inverse transformation. See also *butterfly*.

**fast return register (RTN):** A 16-bit register used to hold the return address for the fast return from interrupt (RETF[D]) instruction.

**G**

**general-purpose input/output pins:** Pins that can be used to supply input signals from an external device or output signals to an external device. These pins are not linked to specific uses; rather, they provide input or output signals for a variety of purposes. These pins include the general-purpose  $\overline{\text{BIO}}$  input pin and XF output pin.

**H**

**hardware interrupt:** An interrupt triggered through physical connections with on-chip peripherals or external devices.

**host port interface (HPI):** An 8-bit parallel interface that the CPU uses to communicate with a host processor.

**HPI control register (HPIC):** A 16-bit register that contains status and control bits for the host port interface (HPI).

**I**

**IFR:** See *interrupt flag register*.

**IMR:** See *interrupt mask register*.

**interrupt:** A condition caused either by an event external to the CPU or by a previously executed instruction that forces the current program to be suspended and causes the processor to execute an interrupt service routine corresponding to the interrupt.

**interrupt flag register (IFR):** A 16-bit memory-mapped register that flags pending interrupts.

**interrupt mask register (IMR):** A 16-bit memory-mapped register that masks external and internal interrupts.

**interrupt mode bit (INTM):** A bit in status register 1 (ST1) that globally masks or enables all interrupts.

**interrupt service routine (ISR):** A module of code that is executed in response to a hardware or software interrupt.

**IPTR:** *interrupt vector pointer.* A 9-bit field in the processor mode status register (PMST) that points to the 128-word page where interrupt vectors reside.

**IR:** *instruction register.* A 16-bit register used to hold a fetched instruction.

**L**

**latency:** The delay between when a condition occurs and when the device reacts to the condition. Also, in a pipeline, the necessary delay between the execution of two instructions to ensure that the values used by the second instruction are correct.

**LSB:** *least significant bit.* The lowest order bit in a word.

**M**

**maskable interrupts:** A hardware interrupt that can be enabled or disabled through software.

**memory map:** A map of the addressable memory space accessed by the '54x processor partitioned according to functionality (memory, registers, etc.).

**memory-mapped registers:** The '54x processor registers mapped into page 0 of the data memory space.

**microcomputer mode:** A mode in which the on-chip ROM is enabled and addressable for program accesses.

**microprocessor/microcomputer (MP/MC) bit:** A bit in the processor mode status register (PMST) that indicates whether the processor is operating in microprocessor or microcomputer mode. See also *microcomputer mode*; *microprocessor mode*.

**microprocessor mode:** A mode in which the on-chip ROM is disabled for program accesses.

**micro stack:** A stack that provides temporary storage for the address of the next instruction to be fetched when the program address generation logic is used to generate sequential addresses in data space.

**MSB:** *most significant bit*. The highest order bit in a word.

**multiplier:** A 17-bit  $\times$  17-bit multiplier that generates a 32-bit product. The multiplier executes multiple operations in a single cycle and operates using either signed or unsigned 2s-complement arithmetic.

**N**

**nested interrupt:** A higher-priority interrupt that must be serviced before completion of the current interrupt service routine (ISR). An executing ISR can set the interrupt mask register (IMR) bits to prevent being suspended by another interrupt.

**nonmaskable interrupt:** An interrupt that can be neither masked by the interrupt mask register (IMR) nor disabled by the INTM bit of status register 1 (ST1).

**O**

**overflow:** A condition in which the result of an arithmetic operation exceeds the capacity of the register used to hold that result.

**overflow flag:** A flag that indicates whether or not an arithmetic operation has exceeded the capacity of the corresponding register.

**P**

**PAGEN:** See *program-address generation logic (PAGEN)*.

**PAR:** *program address register*. A 16-bit register used to address the program-memory operands in FIRS, MACD, MACP, MVDP, MVPD, READA, and WRITA instructions.

**PC:** *program counter*. A 16-bit register that indicates the location of the next instruction to be executed.

**pipeline:** A method of executing instructions in an assembly-line fashion.

**pma:** *program memory address*. A register that provides the address of a multiplier operand that is contained in program memory.

**PMST:** *processor mode status register*. A 16-bit status register that controls the memory configuration of the device. See also *ST0, ST1*.

**pop:** Action of removing a word from a stack.

**program-address generation logic (PAGEN):** Logic circuitry that generates the address for program memory reads and writes, and the address for data memory in instructions that require two data operands. This circuitry can generate one address per machine. See also *data-address generation logic (DAGEN)*.

**program counter (PC):** A 16-bit register that indicates the location of the next instruction to be executed.

**program controller:** Logic circuitry that decodes instructions, manages the pipeline, stores status of operations, and decodes conditional operations.

**program memory:** A memory region used for storing and executing programs.

**push:** Action of placing a word onto a stack.

**R**

**RC:** *repeat counter*. A 16-bit register used to specify the number of times a single instruction is executed.

**register:** A group of bits used for temporarily holding data or for controlling or specifying the status of a device.

**repeat counter (RC):** A 16-bit register used to specify the number of times a single instruction is executed.

**reset:** A means of bringing the CPU to a known state by setting the registers and control bits to predetermined values and signaling execution to start at a specified address.

**REA:** *block-repeat end address.* A 16-bit register that specifies the end address of a code segment to be repeated in repeat mode.

**RSA:** *block-repeat start address.* A 16-bit register that specifies the start address of a code segment to be repeated in repeat mode.

**RTN:** *fast return register.* A 16-bit register used to hold the return address for the fast return from interrupt (RETF[D]) instruction.

**S**

**SARAM:** *single-access RAM.* Memory that can be read/written once during one clock cycle.

**serial port interface:** An on-chip full-duplex serial port interface that provides direct serial communication to serial devices with a minimum of external hardware, such as codecs and serial analog-to-digital (A/D) and digital-to-analog (D/A) converters. Status and control of the serial port is specified in the serial port control register (SPC).

**shifter:** A hardware unit that shifts bits in a word to the left or to the right.

**sign-control logic:** Circuitry used to extend data bits (signed/unsigned) to match the input data format of the multiplier, ALU, and shifter.

**sign extension:** An operation that fills the high order bits of a number with the sign bit.

**software interrupt (SINT):** An interrupt caused by the execution of an INTR or TRAP instruction.

**software wait-state register (SWWSR):** *software wait-state register.* A 16-bit register that selects the number of wait states for the program, data, and I/O spaces of off-chip memory.

**SP:** *stack pointer.* A register that always points to the last element pushed onto the stack.

**ST0:** A 16-bit register that contains '54x status and control bits. See also *PMST, ST1.*

**ST1:** A 16-bit register that contains '54x status and control bits. See also *PMST, ST0.*

**stack:** A block of memory used for storing return addresses for subroutines and interrupt service routines and for storing data.

**stack pointer (SP):** A register that always points to the last element pushed onto the stack.

**T**

**temporary register (T):** A 16-bit register that holds one of the operands for multiply operations, the dynamic shift count for the LACT, ADDT, and SUBT instructions, or the dynamic bit position for the BITT instruction.

**time-division multiplexing (TDM):** The process by which a single serial bus is shared by up to eight '54x devices with each device taking turns to communicate on the bus. There are a total of eight time slots (channels) available. During a time slot, a given device may talk to any combination of devices on the bus.

**transition register (TRN):** A 16-bit register that holds the transition decision for the path to new metrics to perform the Viterbi algorithm.

**TSPC:** *TDM serial port control register.* A 16-bit memory-mapped register that contains status and control bits for the TDM serial port.

**W**

**wait state:** A period of time that the CPU must wait for external program, data, or I/O memory to respond when reading from or writing to that external memory. The CPU waits one extra cycle (one CLKOUT1 cycle) for every wait state.

**warm boot:** The process by which the processor transfers control to the entry address of a previously-loaded program.

**X**

**XF:** *XF status flag.* A bit in status register ST1 that indicates the status of the XF pin.

**XPC:** *program counter extension.* A register that contains the upper 7 bits of the current program memory address.

**Z**

**zero fill:** A method of filling the low or high order bits with zeros when loading a 16-bit number into a 32-bit field.

<b>Total Pages</b>	<b>388</b>		

**Notes**

Cover:

- If your book has a blue and yellow cover, enter 0 (do not count the covers, reference cards, etc.)
- If your book has a self-cover, enter 4 (front and back cover as 4 pages).

Add as many rows as necessary for chapters, filenames, etc.

The Notes and Field Sales Office (FSO) listing count as 2 pages and the print vendor pads the last signature with the correct number of notes pages as needed.

The **Total Pages** should be a multiple of 4. The FSO is included on all documents; add notes page to create even signatures (which must be a multiple of 4).

---

## ***Additional Information for Printer***

☛ Note that *all possible fonts* are listed below. Before sending this book to print, delete fonts from the list that aren't used in this book.

**Fonts Used:** \_\_\_\_\_ Helvetica \_\_\_\_\_  
\_\_\_\_\_ Helvetica Narrow \_\_\_\_\_  
\_\_\_\_\_ Courier \_\_\_\_\_  
\_\_\_\_\_ Symbol A \_\_\_\_\_  
\_\_\_\_\_ Symbol B \_\_\_\_\_  
\_\_\_\_\_ Symbols \_\_\_\_\_  
\_\_\_\_\_ Math A \_\_\_\_\_

**Operating System:** \_\_\_\_\_ SunOS 4.1.3 \_\_\_\_\_

**Authoring/Word Processing Software:** \_\_\_\_\_ Interleaf 5.4.1 \_\_\_\_\_

**Media:** \_\_\_\_\_ 1/4" tape cartridge (DC6150) \_\_\_\_\_

**PostScript Information:** \_\_\_\_\_ All fonts should be self-contained in the PostScript files. PostScript  
\_\_\_\_\_ files are FTPs or written to tape in UNIX TAR format by default; other  
\_\_\_\_\_ formats can be arranged with prior conditions \_\_\_\_\_

**Print Check:**

**Writer:**

Literature Number: SPRU173

Mfg Part #:D425009-9761 revision \*

TDS Job #: 66009

Scheduled printing date: 10-23-96

<b>Print check completed:</b>		
_____	_____	_____
Name	Signature	Date completed

Verify and check the following items against the Postscript printout before a book goes to print. If there are any errors, return this checklist with the hard copy of the book to the writer or formatter.

**Cover**

***Front and Spine***

Do the following match and appear in the correct font and size on the front cover and spine?

- Correct title
- Correct subtitle (if any)
- Correct year
- Is the correct product group on the bottom right-hand side of the front cover (see Doc Plan to verify).

***Back***

- Does the lower left-hand corner read "Printed in U.S.A." followed by the correct month and year for the printing date?
- Is there a correct part number below the printing date (only for books that are shipped in kits)?
- Is there a correct literature number and revision letter in the lower right-hand corner?

**Title Page**

- Does the title match the one on the front cover?
- Does the subtitle match the one on the front cover (if any)?
- Is the TI logo at the bottom of the page with the soy ink and recycle paper logos?

**Important Notice**

- Has the Important Notice page been included?
- Is the copyright year correct?

**Preface**

- Do the running headers match each heading in the Preface?
- Do the footers on odd-numbered pages say *Read This First* (except on page iii).
- Are the sections that appear in the Preface in the following order?
  - About This Manual
  - How To Use This Manual (optional)
    - Are chapter references in this section correct?
  - Notational Conventions
  - Information About Cautions and Warnings (optional)
  - Related Documentation From Texas Instruments
  - Related Documentation — not from TI (optional)
  - FCC Warning (for books that document boards or other hardware)
  - Trademarks
  - If You Need Assistance....
    - Are only relevant phone numbers included?

**Print Check:**

---

**Table of Contents, Lists of Figure, Tables, etc.**

- Does each title in the TOC match the section title? (Watch for overbars (ex.  $\overline{\text{CSTRB}}$ ), capitalization, etc.)
- Does each chapter have a meaningful chapter description?
- Has the dot leader and page number been removed from each chapter description?
- Are all level 1 and 2 headings in the book included in the TOC?
- Do headings in the main TOC that should contain *Example*, *Figure*, *Table*, or *Equation* still include those words? (Sometimes these words are accidentally deleted from the TOC when it is formatted.)
- Do TOC page numbers match the actual page number?
- Do TOC section numbers match the actual sections?
- Are all page numbers correctly tabbed to the right-hand side of the page?
- Do all headings have at least five dots before the page number? ( . . . . )
- Are appendixes listed with the correct letter?
- Are all unnecessary spaces removed from the titles?
- Do page breaks keep logical sections together?

**Chapters, Appendixes**

Verify the Mini Table of Contents (first page of each chapter):

- Do the titles inside the box match the level 1 headings in the chapter?
- Do the heading numbers match?
- Do the page numbers match the location of the heading?
- Are all page numbers correctly tabbed to the right-hand side of the page?
- Are all level 1 headings in the chapter in the mini TOC?
- Does the shading allow all text to be readable?
- Is the book free of NO TAGs? (Scan each chapter for the phrase NO TAG. If you find ONE, return to the writer or a formatter immediately and ask for a NO TAG electronic check of all chapters.)
- Are all running headers and footers positioned correctly?
- Does the running title in the header match the corresponding level one heading?
- Do the footers on the odd-numbered pages show the page number and the correct chapter title?
- Do the footers on even pages show the page number (and module title for a multivolume manual)?
- Are all pages in numerical order with no blank pages in the middle of a chapter?
- Do all page breaks avoid split paragraphs or widowed components?
- Are all graphics placed appropriately? (Verify that no graphics "hang out" in the margins.)
- Is all text in graphics readable?
- Does the chapter end on an even-numbered page?
- If the last page in the chapter is blank, is the header empty?

**Index**

- Does the index end on an even-numbered page?
- Have *Nu* and *Sy* been removed as the first heading(s)?
- Are all letter headings followed by index entries?
- Have you spot-checked at least 6 index entries?
- Are the column breaks logical?
- Does each column begin with one of the following: level 1 entry, index letter, or *entry*, continued?
- Have all "continued" headings been removed from within the column?
- Are all page ranges specified with "to" instead of and en dash (–)?
- Are there em spaces ( ) between the entry and the first page number?

## **IMPORTANT NOTICE**

Texas Instruments (TI) reserves the right to make changes to its products or to discontinue any semiconductor product or service without notice, and advises its customers to obtain the latest version of relevant information to verify, before placing orders, that the information being relied on is current.

TI warrants performance of its semiconductor products and related software to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

Certain applications using semiconductor products may involve potential risks of death, personal injury, or severe property or environmental damage ("Critical Applications").

**TI SEMICONDUCTOR PRODUCTS ARE NOT DESIGNED, INTENDED, AUTHORIZED, OR WARRANTED TO BE SUITABLE FOR USE IN LIFE-SUPPORT APPLICATIONS, DEVICES OR SYSTEMS OR OTHER CRITICAL APPLICATIONS.**

Inclusion of TI products in such applications is understood to be fully at the risk of the customer. Use of TI products in such applications requires the written approval of an appropriate TI officer. Questions concerning potential risk applications should be directed to TI through a local SC sales office.

In order to minimize risks associated with the customer's applications, adequate design and operating safeguards should be provided by the customer to minimize inherent or procedural hazards.

TI assumes no liability for applications assistance, customer product design, software performance, or infringement of patents or services described herein. Nor does TI warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used.
