nRF24LU1

Single Chip 2.4GHz Transceiver with USB Microcontroller and Flash Memory

Product Specification v1.0

Key Features

- nRF24L01 compatible RF transceiver
- Worldwide 2.4GHz ISM band operation
- Up to 2Mbps on air data rate
- Enhanced ShockBurst™ hardware link layer
- Air compatible with nRF24L01, nRF2401A, 02, E1 and E2
- Low cost external ±60ppm 16MHz crystal
- Full speed USB 2.0 compliant device controller
- Up to 12 Mbps USB transfer rate
- 2 control, 10 bulk/interrupt and 2 ISO endpoints
- Dedicated 512 bytes endpoint buffer RAM
- Software controlled pull-up resistor for D+
- PLL for full-speed USB operation
- Voltage regulator, 4.0 to 5.25V supply range
- Enhanced 8-bit 8051 compatible microcontroller
- Reduced instruction cycle time
- 32-bit multiplication-division unit
- 16 kbytes of on-chip flash memory
- 2 kbytes of on-chip SRAM
- 6 general purpose digital input/output pins
- Hardware SPI slave and master, UART
- 3 16-bit timers/counters
- AES encryption/decryption co-processor
- Supports firmware upgrade over USB
- Supports FS2 hardware debugger
- Compact 32-pin 5x5mm QFN package

Applications

- Compact USB dongles for wireless peripherals
- USB dongles for mouse, keyboards and remotes
- USB dongle 3-in-1 desktop bundles
- USB dongle for advanced media center remote controls
- USB dongle for game controllers
- Toys

Liability disclaimer

Nordic Semiconductor ASA reserves the right to make changes without further notice to the product to improve reliability, function or design. Nordic Semiconductor ASA does not assume any liability arising out of the application or use of any product or circuits described herein.

All application information is advisory and does not form part of the specification.

Limiting values

Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the specifications are not implied. Exposure to limiting values for extended periods may affect device reliability.

Life support applications

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Nordic Semiconductor ASA customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Nordic Semiconductor ASA for any damages resulting from such improper use or sale.

Data sheet status	
Objective product specification	This product specification contains target specifications for product development.
Preliminary product specification	This product specification contains preliminary data; supplementary data may be published from Nordic Semiconductor ASA later.
Product specification	This product specification contains final product specifications. Nordic Semiconductor ASA reserves the right to make changes at any time without notice in order to improve design and supply the best possible product.

Writing Conventions

This product specification follows a set of typographic rules that makes the document consistent and easy to read. The following writing conventions are used:

- Commands, bit state conditions, and register names are written in `Courier`.

- Pin names and pin signal conditions are written in `Courier bold`.

- Cross references are <u>underlined and highlighted in blue</u>.

1 Introduction

The nRF24LU1 is a unique single chip solution for compact USB dongles. By integrating a nRF24L01 compatible 2.4GHz RF transceiver it supports a wide range of applications including PC peripherals, sports accessories and game peripherals.

With an air data rate of 2 Mbps combined with full speed USB, supporting up to 12 Mbps, the nRF24LU1 meets the stringent performance requirements of applications such as wireless mouse, game controllers and media center remote controls with displays.

The nRF24LU1 integrates:

- A nRF24L01 compatible 2.4GHz RF transceiver
- A full speed USB 2.0 compliant device controller
- An 8-bit microcontroller
- 16 kbytes of flash memory

All this is packaged on a compact 5x5mm package, low cost external BOM.

With an internal voltage regulator that enables the chip to be powered directly from the USB bus, it does not require an external voltage regulator, saving cost and board space. With a fully integrated RF synthesizer and PLL for the USB no external loop filters, resonators or VCO varactor diodes are required. All that is needed is a low cost ±60ppm 16MHz crystal, matching circuitry and the antenna.

The main benefits of nRF24LU1 are:

- Very compact USB dongle
- Low cost external BOM
- No need for an external voltage regulator
- Single low cost ±60ppm 16MHz crystal
- Flash memory for firmware upgrades

1.1   Features

Features of the nRF24LU1 include:

- Fast 8-bit MCU:
  - ▸ Intel MCS 51 compliant instruction set
  - ▸ Reduced instruction cycle time, up to 12x compared to legacy 8051
  - ▸ 32 bit multiplication – division unit
- Memory:
  - ▸ 16 kbytes of on-chip flash memory with security features
  - ▸ 2 kbytes of on-chip RAM memory
  - ▸ Pre-programmed USB bootloader in the on-chip flash memory.
- 6 programmable digital input/output pins configurable as:
  - ▸ GPIO
  - ▸ SPI master
  - ▸ SPI slave
  - ▸ External interrupts
  - ▸ Timer inputs
  - ▸ Full duplex serial port
  - ▸ Debug interface
- High-performance 2.4GHz RF-transceiver
  - ▸ True single chip GFSK transceiver
  - ▸ Complete OSI Link Layer in hardware
  - ▸ Enhanced ShockBurst™
  - ▸ Auto ACK & retransmit
  - ▸ Address and CRC computation
  - ▸ On the air data rate 1 or 2Mbps
  - ▸ Digital interface (SPI) speed 0-8 Mbps
  - ▸ 125 RF channel operation
  - ▸ Short switching time enable frequency hopping
  - ▸ Fully compatible with nRF24LXX
  - ▸ RF compatible with nRF2401A, nRF2402, nRF24E1, nRF24E2 in 1 Mbps mode
- AES encryption/decryption HW-block with 128 bits key length
  - ▸ ECB – Electronic Code Book mode
  - ▸ CBC – Cipher Block Chaining
  - ▸ CFB – Cipher FeedBack mode
  - ▸ OFB – Output FeedBack mode
  - ▸ CTR – Counter mode
- Full speed USB 2.0 compliant device controller supporting:
  - ▸ Data transfer rates up to 12 Mbit/s
  - ▸ Control, Interrupt, Bulk and ISO data transfer
  - ▸ Endpoint 0 for control
  - ▸ 5 input and 5 output Bulk/Interrupt endpoints
  - ▸ 1 input and 1 output iso-synchronous endpoints
  - ▸ Total 512 bytes of USB buffer endpoint memory sharable between endpoints
  - ▸ On-chip USB transceiver PHY
  - ▸ On-chip pull-up resistor on D+ line with software controlled disconnect
- Power management function:
  - ▸ Low power design supporting fully static stop/ standby/ suspend modes
  - ▸ Programmable MCU clock frequency from 64 kHz to 16 MHz
  - ▸ On-chip voltage regulators supporting low power mode (supplied from USB power)
  - ▸ Watchdog and wakeup functionality running in low power mode

- On-chip oscillator and PLL to obtain full speed USB operation and to reduce the need for external components
- On-chip power on reset generator and brown-out detector
- On-chip support for HW debugger, supported by Keil development tools.
- Complete firmware platform available:
  - ▸ Hardware abstraction layer (HAL) Functions
  - ▸ USB library Functions
  - ▸ Standard and HID specific USB Requests and Descriptors
  - ▸ nRF24LU1 Library functions
  - ▸ AES HAL
  - ▸ Application examples
  - ▸ Device Firmware Upgrade

2 Pin Information

2.1 Pin Assignments
Figure 3. nRF24LU1 pin assignment (top view) for a QFN32 5x5 mm package.

2.2   Pin Functions

Pin	Name	Type	Description
21, 22	ANT1, ANT2	RF	Antenna connection
5, 4	D-, D+	Digital I/O	USB data
28, 29	DEC1, DEC2	Power	Positive Digital Supply output for de-coupling purposes
25	IREF	Analog Input	Reference current
10, 11, 13, 14, 15, 16	P0.0 – P0.5	Digital I/O	General purpose data Port 0, bit 0 - 5
7	PROG	Digital Input	Reserved for programming the flash
8	RESET	Digital Input	Reset for MCU, active low
2	VBUS	Power	USB power connection
1, 3, 9, 19, 24, 27	VDD	Power	Alternative power supply pins. The VDD pins must always be connected and de-coupled externally.
20	VDD_PA	Power Output	Power Supply (+1.8V) to Power Amplifier
6, 12, 17, 18, 23, 26, 30	VSS	Power	Ground (0V)
32, 31	XC1, XC2	Analog Input	Crystal connection

Table 2. nRF24LU1 pin functions.

2.2.1   Antenna pins

ANT1 and ANT2 are connections for the external antenna (both receive and transmit).

2.2.2   USB pins

D- and D+ are the connections to the USB data lines. External ESD protection is recommended.

2.2.3   Power supply pins

VBUS and VSS are the power supply and ground pins. The nRF24LU1 can operate from a single power supply.

The nRF24LU1 contains an on-chip regulator that produces +3.3V on the VDD pins, from the VBUS supply line (4.0 – 5.25 V). Alternatively, the VBUS pin can be left open and the VDD pins may be fed from an external 3.3V supply. In this case, the on-chip 3.3V regulator is switched off.

Additional on-chip regulators produce voltages for internal analog and digital functions blocks. External decoupling capacitors are required on DEC1 and DEC2.

VDD_PA is a 1.8V output that is used to switch on an external RF Power Amplifier.

2.2.4   PROG pin

When set high this pin enables external flash programming and Port 0 is configured as a slave SPI port. The PROG pin needs an external pull-down resistor.

2.2.5   Reference current pin

IREF pin must be connected to an external resistor.

2.2.6 Port pins

`P0.0` – `P0.5` are six general purpose I/O pins. Their functions are described in .

2.2.7 External RESET Pin

A logic 0 on the `RESET` pin forces the nRF24LU1 to a known start-up state.

2.2.8 Crystal oscillator pins

`XC1` and `XC2` are connections to an external crystal.

3   Absolute Maximum Ratings

Maximum ratings are the extreme limits that you can expose the nRF24LU1 to without permanently damaging it. Exposure to absolute maximum ratings for prolonged periods of time may affect device reliability.

Operating conditions	Minimum	Maximum	Units
Supply voltages			
VBUS	-0.3V	+5.75	V
VSS		0	V
VDD	+3.0	+3.6	V
Input voltage			
VI	-0.3	+3.6	V
Total Power Dissipation			
PD (TA=85°C)		180	mW
Temperatures			
Operating Temperature	-40	+85	°C
Storage Temperature	-40	+125	°C

Table 3. Absolute maximum ratings

4   Operating Conditions

Symbol	Parameter (condition)	Notes	Min.	Typ.	Max.	Units
VBUS	Supply voltage		4.0	5	5.25	V
VDD	Alternative supply voltage		3.05	3.27	3.5	V
TEMP	Operating Temperature		-40	+27	+85	ºC

5 Electrical Specifications

This section contains electrical and timing specifications.

5.1 Power consumption and timing characteristics

Symbol	Parameter (condition)	Notes	Min.	Typ.	Max.	Units
ISUP	Average current in supply mode	a		24		mA
ISTANDBY	Supply current in standby mode	b		480		µA
	MCU					
IMCU16MPLL	Running @ 16MHz, generated from PLL			6		mA
IMCU12MPLL	Running @ 12MHz, generated from PLL			5		mA
IMCU8MPLL	Running @ 8MHz, generated from PLL			4		mA
IMCU4MPLL	Running @ 4MHz, generated from PLL			3		mA
IMCU1.6MPLL	Running @ 1.6MHz, generated from PLL			2.4		mA
IMCU4MXO	Running @ 4MHz, generated from XO			2.4		mA
IMCU1.6MXO	Running @ 1.6MHz, generated from XO			1.75		mA
IMCU.32MXO	Running @ 0.32MHz, generated from XO			1.4		mA
IMCU64KXO	Running @ 0.064MHz, generated from XO			1.35		mA
Trst_act	From RESET to MCU active				2	ms
Tint_act	From INTERRUPT to MCU active				300	µs
Tact_stby	MCU from active to standby	c			32	µs
	RF Transceiver					
ITX	RF Transceiver TX current @0dBm output power			11		mA
IRX	RF Transceiver RX current			12		mA
Trfpwd_act	RF Transceiver from standby to active	c			130	µs
Trst_radio	From RESET to RF Transceiver power down				50	ms
	USB					
IUSB	USB active current			4.5		mA
Tusb_wh	USB wakeup from host				500	µs
Tusb_wmcu	USB wakeup from MCU				300	µs
Tusbact_susp	USB from active to suspend	c			32	µs
	PLL					
Tplloff_on	PLL from off to on time	c d			250	µs
Tpllon_off	PLL from on to off time	c d			32	µs

a. For radio receive at 2Mbps and USB transmit
b. This is accurate for when MCU is in standby, USB is suspended and the RF Transceiver is in standby
c. Measured from start of the software instruction which executes the change of mode
d. Only possible when USB is in suspend mode

Table 5. Power consumption and timing characteristics

5.2 RF transceiver characteristics

Symbol	Parameter (conditions)	Notes	Min.	Typ.	Max.	Units
	General RF conditions					
fOP	Operating frequency	a	2400		2525	MHz
PLLres	PLL Programming resolution			1		MHz
fXTAL	Crystal frequency			16		MHz
Df1M	Frequency deviation @ 1Mbps			±160		kHz
Df2M	Frequency deviation @ 2Mbps			±320		kHz
RGFSK	Air Data rate	b	1000		2000	kbps
FCHAN-NEL 1M	Non-overlapping channel spacing @ 1Mbps	c		1		MHz
FCHAN-NEL 2M	Non-overlapping channel spacing @ 2Mbps	c		2		MHz
	RF Transmitter operation					
PRF	Maximum Output Power	d		0	+4	dBm
PRFC	RF Power Control Range		16	18	20	dB
PRFCR	RF Power Accuracy				±4	dB
PBW2	20dB Bandwidth for Modulated Carrier (2Mbps)			1900	2040	kHz
PBW1	20dB Bandwidth for Modulated Carrier (1Mbps)			940	1070	kHz
PRF1	1st Adjacent Channel Transmit Power 2MHz				-18	dBc
PRF2	2nd Adjacent Channel Transmit Power 4MHz				-38	dBc
	RF Receiver operation					
RXmax	Maximum received signal at <0.1% BER			0		dBm
RXSENS	Sensitivity (0.1%BER) @2Mbps			-82		dBm
RXSENS	Sensitivity at (0.1%BER) @1Mbps			-85		dBm
RX selectivity according to ETSI EN 300 440-1 V1.3.1 (2001-09) page 27						
C/ICO	C/I Co-channel (@2Mbps)	e		7		dB
C/I1ST	1st Adjacent Channel Selectivity C/I 2MHz			1		dB
C/I2ND	2nd Adjacent Channel Selectivity C/I 4MHz			-21		dB
C/I3RD	3rd Adjacent Channel Selectivity C/I 6MHz			-27		dB
C/ICO	C/I Co-channel (@1Mbps)	f		9		dB
C/I1ST	1st Adjacent Channel Selectivity C/I 1MHz			8		dB
C/I2ND	2nd Adjacent Channel Selectivity C/I 2MHz			-22		dB
C/I3RD	3rd Adjacent Channel Selectivity C/I 3MHz			-30		dB

Symbol	Parameter (conditions)	Notes	Min.	Typ.	Max.	Units
RX selectivity with RF Transceiver equal modulation on interfering signal						
C/ICO	C/I Co-channel (@2Mbps) (Modulated carrier)	e		11		dB
C/I1ST	1st Adjacent Channel Selectivity C/I 2MHz			4		dB
C/I2ND	2nd Adjacent Channel Selectivity C/I 4MHz			-20		dB
C/I3RD	3rd Adjacent Channel Selectivity C/I 6MHz			-27		dB
C/ICO	C/I Co-channel (@1Mbps)	f		12		dB
C/I1ST	1st Adjacent Channel Selectivity C/I 1MHz			8		dB
C/I2ND	2nd Adjacent Channel Selectivity C/I 2MHz			-21		dB
C/I3RD	3rd Adjacent Channel Selectivity C/I 3MHz			-30		dB

a. Usable band is determined by local regulations
b. Data rate in each burst on-air
c. The minimum channel spacing is 1Mhz
d. Antenna load impedance = 15W+j88W
e. Data rate is 2Mbps for the following C/I measurements
f. Data rate is 1Mbps for the following C/I measurements

Table 6. RF Transceiver specifications

5.3   USB interface

The USB interface electrical performance is compliant with the USB specification 2.0.

Characteristic	Symbol	Conditions	Min.	Typ.	Max	Unit
Electrical characteristics						
Input high voltage (driven)	VIH		2.0			V
Input low voltage	VIL				0.8	V
Differential input sensitivity	VDI	|(D+) − (D-)|	0.2			V
Differential common mode range	VCM	Includes VDI range	0.8		2.5	V
Single ended receiver threshold	VSE		0.8		2.0	V
Single ended receiver hysteresis	VSEH			200		mV
Output low voltage	VOL		0		0.3	V
Output high voltage	VOH		2.8		3.6	V
Differential output signal cross-point voltage	VCRS		1.3		2.0	V
Internal pull-up resistor (Standby mode)	RPU1		900	1100	1575	W
Internal pull-up resistor (Active mode)	RPU2		1425	2100	3090	W
Termination voltage connected to RPU	VTRM		3.05		3.5	V
Output driver resistance (does not include the series resistance)	ZDRV	Steady state drive		15		W
Timing characteristics						
Driver rise time	TFR	CL=50pF	4		20	ns
Driver fall time	TFF	CL=50pF	4		20	ns
Rise/fall time matching	TFRFF	TRF / TFF	90		111	%
Transceiver pad capacitance	CIN	Pad to ground			20	pF

Table 7. USB interface characteristics

5.4   Flash memory

Characteristic	Symbol	Conditions	Min.	Typ.	Max	Unit
Endurance (20 ms erase+20 µs write)	Nendur		1000			cycles
Data retention	Tret	25°C	100			years

Table 8. Flash memory characteristics

5.5 Crystal specifications

Symbol	Parameter (condition)	Notes	Min.	Typ.	Max.	Units
fXTAL	Crystal frequency			16.00		MHz
fTOL	Frequency tolerance	a b			±60	ppm
ESR	Equivalent Series Resistance				100	W
C0	Parallel equivalent capacitance				7.0	pF
CL	Load capacitance		8		16	pF

a. Frequency accuracy including; tolerance at 25ºC, temperature drift, aging and crystal loading.
b. Frequency regulations in certain regions sets tighter requirements to frequency tolerance (for example, Japan and Korea max. +/- 50ppm).

Table 9. Crystal specifications

5.6 DC Electrical Characteristics

Symbol	Parameter (condition)	Notes	Min.	Typ.	Max.	Units
	Operating conditions					
VBUS	Supply voltage		4.0	5.0	5.25	V
TEMP	Operating Temperature		-40	+27	+85	ºC
	On-chip voltage regulators					
VDD	Output voltage	a	3.05	3.27	3.5	V
IVDD	External load current				2	mA
VDD_PA	PA switch output		1.7	1.8	1.9	V

a. Also valid for VDD input voltage.

Table 10. DC characteristics

Symbol	Parameter (condition)	Notes	Min.	Typ.	Max.	Units
VIH	HIGH level input voltage		0.7 VDD		VDD	V
VIL	LOW level input voltage		VSS		0.3 VDD	V

Table 11. Digital input pin

Symbol	Parameter (condition)	Notes	Min.	Typ.	Max.	Units
VOH	HIGH level output voltage (IOH= -1.0mA)	a	VDD-0.3		VDD	V
VOL	LOW level output voltage (IOL= 1.0mA))		VSS		0.3	V

a. When the nRF24LU1 is supplied from VBUS, there is a limit (IVDD) on the current that can be drawn from VDD by external devices. Current sourced by high outputs are supplied to external devices for this purpose.

Table 12. Digital output pin

6 RF Transceiver

The nRF24LU1 uses a 2.4GHz RF Transceiver with an embedded hardware link layer (Enhanced Shock-Burst™), designed for ultra low power wireless applications. The RF Transceiver is designed for operation in the world wide ISM frequency band at 2.400 - 2.4835GHz and is fully compatible with nRF24L01.

The RF Transceiver is configured and operated through a Serial Peripheral Interface (SPI). Through this interface the register map is available. The register map contains all configuration registers in the RF Transceiver and is accessible in all operation modes of the chip.

The embedded baseband protocol engine (Enhanced ShockBurst™) is based on packet communication and supports various modes from manual operation to advanced autonomous protocol operation. Internal FIFOs ensure a smooth data flow between the radio front end and the system's MCU.

The radio front end uses GFSK modulation. It has user configurable parameters like frequency channel, output power and air data rate.

The air data rate supported by the RF Transceiver is configurable to 1Mbps or 2Mbps.

6.1 Features

Features of the RF Transceiver include:

- Radio
  - Worldwide 2.4GHz ISM band operation
  - 126 RF channels
  - GFSK modulation
  - 1 and 2Mbps air data rate
  - 1MHz non-overlapping channel spacing at 1Mbps
  - 2MHz non-overlapping channel spacing at 2Mbps
- Transmitter
  - Programmable output power: 0, -6, -12 or -18dBm
- Receiver
  - Integrated channel filters
  - -82dBm sensitivity at 2Mbps
  - -85dBm sensitivity at 1Mbps
  - Programmable LNA gain
- RF Synthesizer
  - Fully integrated synthesizer
  - No external loop filer, VCO varactor diode or resonator
  - Accepts low cost ±60ppm 16MHz crystal
- Enhanced ShockBurst™
  - 1 to 32 bytes dynamic payload length
  - Automatic packet handling
  - Auto packet transaction handling
  - Up to 6 data pipe MultiCeiver™ for 6:1 star networks

6.2 Block diagram
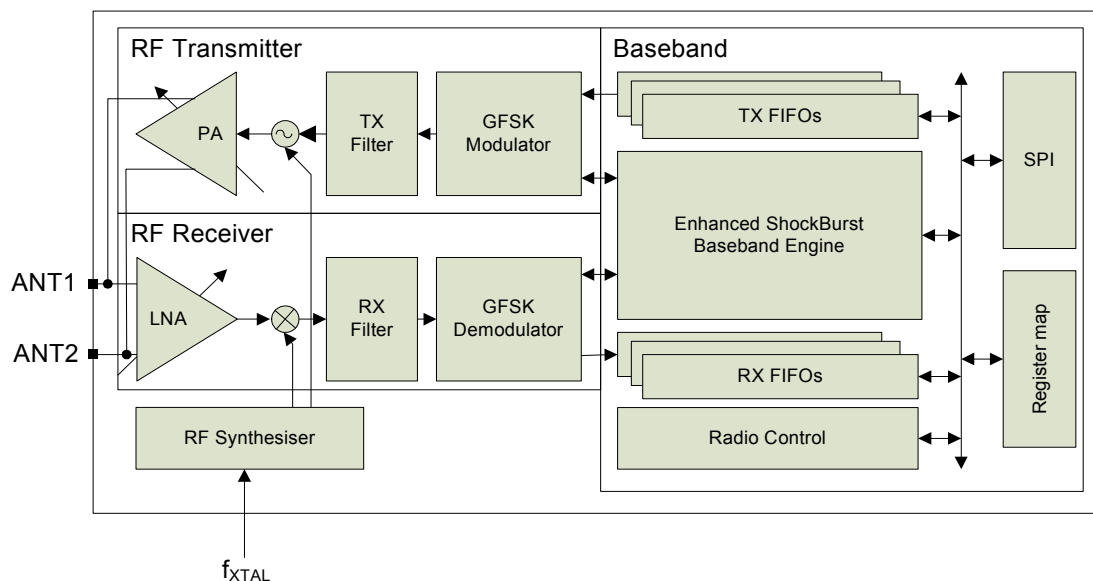

Figure 4. RF Transceiver block diagram

6.3 Radio control

This section describes the different modes the RF Transceiver can operate in and the parameters used to control the radio.

The RF Transceiver has a built-in state machine that controls the transitions between the different operating modes of the transceiver. The state machine takes input from user defined register values and internal signals.

6.3.1 Operational modes

The RF Transceiver can be configured in four main modes of operation (power down, standby, TX and RX modes).

6.3.1.1 State diagram

At the end of the reset sequence, the RF Transceiver enters the Power Down mode. When the RF Transceiver enters Power Down mode the MCU can control the RF Transceiver through the SPI. Three types of states are illustrated in the state diagram:

- Recommended operating mode: a state used during normal operation.
- Possible operating mode: a state that can be used, but it is not used during normal operation.
- Transition state: a time limited state used during start up of the oscillator and settling of the PLL.

The state diagram below (Figure 5.) shows the modes the RF Transceiver can operate in and how they are accessed.

.
Figure 5. Radio control state diagram

6.3.1.2   Power down mode

In power down mode the RF Transceiver is disabled with minimal current consumption but all register values are maintained and available from the SPI. For start up time see Table 14. on page 30. Power down mode is entered by setting the PWR_UP bit in the CONFIG register low.

6.3.1.3   Standby modes

By setting the PWR_UP bit in the CONFIG register to 1, the device enters standby-I mode. Standby-I mode is used to minimize average current consumption while maintaining short start up times. In this mode part of the crystal oscillator is active. When rfce bit in the RFCON register is set low the nRF24L01 returns to standby-I mode from both the TX and RX modes.

In standby-II mode extra clock buffers are active compared to standby-I mode and much more current is used compared to standby-I mode. Standby-II occurs when rfce bit in the RFCON register is held high on a PTX device with empty TX FIFO. If a new packet is uploaded to the TX FIFO, the PLL starts and the packet is transmitted.

The register values are maintained during standby modes and the SPI may be activated. For start up time see .

6.3.1.4   RX mode

RX (Receive) is an active mode and when the RF Transceiver is in this mode it acts as a receiver. To enter this mode, the RF Transceiver must have the PWR_UP bit set high, PRIM_RX bit set high and rfce bit in the RFCON register enabled.

In this mode the receiver demodulates the signals from the RF channel, constantly presenting the demodulated data to the baseband protocol engine. The baseband protocol engine constantly searches for a valid packet. If a valid packet is found (by a matching address and a valid CRC), the payload of the packet is presented in a vacant slot in the RX FIFO. If the RX FIFO is full, the received packet is discarded.

The RF Transceiver remains in RX mode until the MCU configures it to standby-I mode or power down mode. If the automatic protocol features (Enhanced ShockBurst™) in the baseband protocol engine are enabled, the RF Transceiver can enter other modes in order to execute the protocol.

In RX mode a carrier detect signal is available. The carrier detect is a signal that is set high when a RF signal is detected inside the receiving frequency channel. The signal must be FSK modulated for a secure detection. Other signals can also be detected. The Carrier Detect (CD) is set high when an RF signal is detected in RX mode, otherwise CD is low. The internal CD signal is filtered before presented to CD register. The RF signal must be present for at least 128µs before the CD is set high.

6.3.1.5   TX mode

The TX mode is an active mode where the nRF24LU1 transmits a packet. To enter this mode, the RF Transceiver must have the PWR_UP bit set high, PRIM_RX bit set low, a payload in the TX FIFO and, a high pulse on the rfce bit in the RFCON register for more than 10µs.

The RF Transceiver stays in TX mode until it finishes transmitting a current packet. If rfce bit in the RFCON register is disabled nRF24LU1 returns to standby-I mode. If rfce bit in the RFCON register is enabled, the next action is determined by the status of the TX FIFO. If the TX FIFO is not empty the RF Transceiver remains in TX mode, transmitting the next packet. If the TX FIFO is empty the RF Transceiver goes into standby-II mode.The RF Transceiver transmitter PLL operates in open loop when in TX mode. It is important to never keep the RF Transceiver in TX mode for more than 4ms at a time. If the auto retransmit is enabled, the RF Transceiver is never in TX mode long enough to disobey this rule.

6.3.1.6 Operational modes configuration

The following table (Table 13.) describes how to configure the operational modes.

Mode	PWR_UP register	PRIM_RX register	CE	FIFO state
RX mode	1	1	1	-
TX mode	1	0	1	Data in TX FIFO. Will empty all levels in TX FIFO[a].
TX mode	1	0	minimum 10µs high pulse	Data in TX FIFO.Will empty one level in TX FIFO[b].
Standby-II	1	0	1	TX FIFO empty
Standby-I	1	-	0	No ongoing packet transmission
Power Down	0	-	-	-

   a. In this operating mode if `rfce` is held high the TX FIFO is emptied and all necessary ACK and possible retransmits are carried out. The transmission continues as long as the TX FIFO is refilled. If the TX FIFO is empty when the `rfce` is still high, RF Transceiver enters standby-II mode. In this mode the transmission of a packet is started as soon as the `rfcsn` is set high after a upload (UL) of a packet to TX FIFO.

   b. This operating mode pulses the `rfce` high for at least 10µs. This allows one packet to be transmitted. This is the normal operating mode. After the packet is transmitted, the RF Transceiver enters standby-I mode.

Table 13. RF Transceiver main modes

6.3.1.7 Timing information

The timing information in this section is related to the transitions between modes and the timing for the `rfce` bit in the `RFCON` register. The transition from TX mode to RX mode or vice versa is the same as the transition from standby-I to TX mode or RX mode,Tstby2a.

Name	RF Transceiver	Max.	Min.	Comments
Tpd2stby	Power Down è Standby mode	150µs		
Tstby2a	Standby modes è TX/RX mode	130µs		
Thce	Minimum `rfce` high		10µs	
Tpece2csn	Delay from `rfce` positive edge to `rfcsn` low		4µs	

Table 14. Operational timing of the RF Transceiver

6.3.2 Air data rate

The air data rate is the modulated signaling rate the RF Transceiver uses when transmitting and receiving data.

The air data rate can be 1Mbps or 2Mbps. The 1Mbps data rate gives 3dB better receiver sensitivity compared to 2Mbps. High air data rate means lower average current consumption and reduced probability of on-air collisions.

The air data rate is set by the `RF_DR` bit in the `RF_SETUP` register.

A transmitter and a receiver must be programmed with the same air data rate to communicate.

For compatibility with nRF2401A, nRF24E1, nRF2402 and nRF24E2 the air data rate must be set to 1Mbps.

6.3.3 RF channel frequency

The RF channel frequency determines the center of the channel used by the RF Transceiver. The channel occupies a bandwidth of 1MHz at 1Mbps and 2MHz at 2Mbps. The RF Transceiver can operate on frequencies from 2.400GHz to 2.525GHz. The resolution of the RF channel frequency setting is 1MHz.

At 2Mbps the channel occupies a bandwidth wider than the resolution of the RF channel frequency setting. To ensure non-overlapping channels in 2Mbps mode, the channel spacing must be 2MHz or more. At 1Mbps the channel bandwidth is the same as the resolution of the RF frequency setting.

The RF channel frequency is set by the `RF_CH` register according to the following formula:

$F0 = 2400 + RF\_CH$ [MHz]

A transmitter and a receiver must be programmed with the same RF channel frequency to be able to communicate with each other.

6.3.4 PA control

The PA control is used to set the output power from the RF Transceiver power amplifier (PA). In TX mode PA control has four programmable steps, see Table 15.

The PA control is set by the `RF_PWR` bits in the `RF_SETUP` register.

SPI RF SETUP (`RF_PWR`)	RF output power
11	0dBm
10	-6dBm
01	-12dBm
00	-18dBm

Conditions: VDD = 3.3V, VSS = 0V, TA = 25ºC, Load impedance = 15 W+j88 W.

Table 15. RF output power setting for the RF Transceiver

6.3.5   LNA gain

The gain in the Low Noise Amplifier (LNA) in the RF Transceiver receiver is controlled by the LNA gain set-ting. The LNA gain makes it possible to reduce the current consumption in RX mode with 0.8mA at the cost of 1.5dB reduction in receiver sensitivity.

The LNA gain has two steps and is set by the `LNA_HCURR` bit in the `RF_SETUP` register.

6.3.6   RX/TX control

The RX/TX control is set by `PRIM_RX` bit in the `CONFIG` register and sets the RF Transceiver in transmit/receive.

6.4   Enhanced ShockBurst™

Enhanced ShockBurst™ is a packet based data link layer that features automatic packet assembly and timing, automatic acknowledgement and re-transmissions of packets. Enhanced ShockBurst™ enables the implementation of ultra low power, high performance communication. The Enhanced ShockBurst™ features enable significant improvements of power efficiency for bi-directional and uni-directional systems.

6.4.1   Features

The main features of Enhanced ShockBurst™ are:

- 1 to 32 bytes dynamic payload length
- Automatic packet handling
- Auto packet transaction handling
    - ▸ Auto Acknowledgement
    - ▸ Auto retransmit
- 6 data pipe MultiCeiver™ for 1:6 star networks

6.4.2   Enhanced ShockBurst™ overview

Enhanced ShockBurst™ uses ShockBurst™ for automatic packet handling and timing. During transmit, ShockBurst™ assembles the packet and clocks the bits in the data packet into the transmitter for transmission. During receive, ShockBurst™ constantly searches for a valid address in the demodulated signal. When ShockBurst™ finds a valid address, it processes the rest of the packet and validates it by CRC. If the packet is valid the payload is moved into the RX FIFO. The high speed bit handling and timing is controlled by ShockBurst™.

Enhanced ShockBurst™ features automatic packet transaction handling that enables the implementation of a reliable bi-directional data link. An Enhanced ShockBurst™ packet transaction is a packet exchange between two transceivers, where one transceiver is the Primary Receiver (PRX) and the other is the Primary Transmitter (PTX). An Enhanced ShockBurst™ packet transaction is always initiated by a packet transmission from the PTX, the transaction is complete when the PTX has received an acknowledgment packet (ACK packet) from the PRX.

The automatic packet transaction handling works as follows:

1. The user initiates the transaction by transmitting a data packet from the PTX to the PRX. Enhanced ShockBurst™ automatically sets the PTX in receive mode to wait for the ACK packet.
2. If the packet is received by the PRX, Enhanced ShockBurst™ automatically assembles and transmits an acknowledgment packet (ACK packet) to the PTX before returning to receive mode.
3. If the PTX does not receive the ACK packet within a set time, Enhanced ShockBurst™ automatically retransmits the original data packet and sets the PTX in receive mode to wait for the ACK packet.

The PRX can attach user data to the ACK packet enabling a bi-directional data link. The Enhanced ShockBurst™ is highly configurable; it is possible to configure parameters such as maximum number of retransmits and the delay from one transmission to the next retransmission. All automatic handling is done without involvement of the MCU.

6.4.3 Enhanced Shockburst™ packet format

The format of the Enhanced ShockBurst™ packet is described in this section. The Enhanced Shock-Burst™ packet contains a preamble field, address field, packet control field, payload field and a CRC field. Figure 6. shows the packet format with MSB to the left.

Preamble 1 byte	Address 3-5 byte	Packet Control Field 9 bit	Payload 0 - 32 byte	CRC 1-2 byte
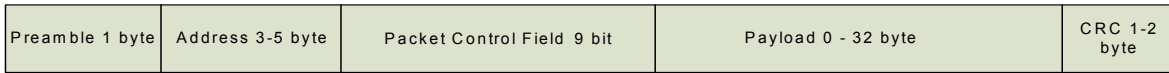

Figure 6. An Enhanced ShockBurst™ packet with payload (0-32 bytes)

6.4.3.1 Preamble

The preamble is a bit sequence used to detect 0 and 1 levels in the receiver. The preamble is one byte long and is either 01010101 or 10101010. If the first bit in the address is 1 the preamble is automatically set to 10101010 and if the first bit is 0 the preamble is automatically set to 01010101. This is done to ensure there are enough transitions in the preamble to stabilize the receiver.

6.4.3.2 Address

This is the address for the receiver. An address ensures that the correct packet is detected by the receiver. The address field can be configured to 3, 4 or, 5 bytes long with the AW register.

> **Note:** Addresses where the level shifts only one time (that is, 000FFFFFFF) can often be detected in noise and can give a false detection, which may give a raised Packet-Error-Rate. Addresses as a continuation of the preamble (hi-low toggling) raises the Packet-Error-Rate.

6.4.3.3 Packet control field

Figure 7. shows the format of the 9 bit packet control field, MSB to the left.

Payload length 6 bit	PID 2 bit	NO_ACK 1 bit
Figure 7. Packet control field

The packet control field contains a 6 bit payload length field, a 2 bit PID (Packet Identity) field and, a 1 bit `NO_ACK flag.`

Payload length

This 6 bit field specifies the length of the payload in bytes. The length of the payload can be from 0 to 32 bytes.

Coding: 000000 = 0 byte (only used in empty ACK packets.) 100000 = 32 byte, 100001 = Don't care.

This field is only used if the Dynamic Payload Length function is enabled.

PID (Packet identification)

The 2 bit PID field is used to detect if the received packet is new or retransmitted. PID prevents the PRX device from presenting the same payload more than once to the MCU. The PID field is incremented at the TX side for each new packet received through the SPI. The PID and CRC fields (see section 6.4.3.5 on page 35) are used by the PRX device to determine if a packet is retransmitted or new. When several data packets are lost on the link, the PID fields may become equal to the last received PID. If a packet has the same PID as the previous packet, the RF Transceiver compares the CRC sums from both packets. If the CRC sums are also equal, the last received packet is considered a copy of the previously received packet and discarded.

No Acknowledgment flag (`NO_ACK`)

The Selective Auto Acknowledgement feature controls the NO_ACK flag.

This flag is only used when the auto acknowledgement feature is used. Setting the flag high, tells the receiver that the packet is not to be auto acknowledged.

6.4.3.4 Payload

The payload is the user defined content of the packet. It can be 0 to 32 bytes wide and is transmitted on-air when it is uploaded (unmodified) to the device.

6.4.3.5 CRC (Cyclic Redundancy Check)

The CRC is the error detection mechanism in the packet. It may either be 1 or 2 bytes and is calculated over the address, Packet Control Field, and Payload.
The polynomial for 1 byte CRC is $X^8 + X^2 + X + 1$. Initial value 0xFF
The polynomial for 2 byte CRC is $X^{16} + X^{12} + X^5 + 1$. Initial value 0xFFFF

No packet is accepted by Enhanced ShockBurst™ if the CRC fails.

6.4.4 Automatic packet handling

Enhanced ShockBurst™ uses ShockBurst™ for automatic packet handling. The functions are:

- Static and dynamic payload length
- Automatic packet assembly
- Automatic packet validation
- Automatic packet disassembly

6.4.4.1 Static and dynamic payload length

The Enhanced ShockBurst™ provides two alternatives for handling payload lengths, static and dynamic.

The default alternative is static payload length. With static payload length all packets between a transmitter and a receiver have the same length. Static payload length is set by the RX_PW_Px registers on the receiver side. The payload length on the transmitter side is set by the number of bytes clocked into the TX_FIFO and must equal the value in the RX_PW_Px register on the receiver side.

Dynamic Payload Length (DPL) is an alternative to static payload length. DPL enables the transmitter to send packets with variable payload length to the receiver. This means that for a system with different payload lengths it is not necessary to scale the packet length to the longest payload.

With the DPL feature the RF Transceiver can decode the payload length of the received packet automatically instead of using the `RX_PW_Px` registers. The MCU can read the length of the received payload by using the `R_RX_PL_WID` command.

In order to enable DPL the `EN_DPL` bit in the `FEATURE` register must be set. In RX mode the `DYNPD` register must be set. A PTX that transmits to a PRX with DPL enabled must have the `DPL_P0` bit in `DYNPD` set.

6.4.4.2 Automatic packet assembly

The automatic packet assembly assembles the preamble, address, packet control field, payload and CRC to make a complete packet before it is transmitted.

Preamble

The preamble is automatically generated based on the address field.

Address

The address is fetched from the TX_ADDR register. The address field can be configured to 3, 4 or 5 bytes long with the AW register.

Packet control field

For the static packet length option the payload length field is not used. With DPL enabled, the value in the payload length field is automatically set to the number of bytes in the payload clocked into the TX FIFO.

The transmitter increments the PID field each time it generates a new packet and uses the same PID on packets that are retransmitted. Refer to the left flow chart in

The PTX can set the `NO_ACK` flag bit in the Packet Control Field with this command:

`W_TX_PAYLOAD_NOACK`

However, the function must first be enabled in the `FEATURE` register by setting the `EN_DYN_ACK` bit. When you use this option the PTX goes directly to standby-I mode after transmitting the packet. The PRX does not transmit an ACK packet when it receives the packet.

Payload

The payload is fetched from the TX FIFO.

CRC

The CRC is automatically calculated based on the packet content with the polynomials in . The number of bytes in the CRC is set by the `CRCO` bit in the CONFIG register.

6.4.4.3   Automatic packet validation

Enhanced ShockBurst™ features automatic packet validation. In receive mode the RF Transceiver is constantly searching for a valid address (given in the RX_ADDR registers). If a valid address is detected Enhanced ShockBurst™ starts to validate the packet.

With static packet length Enhanced ShockBurst™ captures the packet according to the length given by the RX_PW register. With DPL, Enhanced ShockBurst™ captures the packet according to the payload length field in the packet control field. After capturing the packet Enhanced ShockBurst™ performs CRC.

If the CRC is valid, Enhanced ShockBurst™ checks PID. The received PID is compared with the previous received PID. If the PID fields are different, the packet is considered new. If the PID fields are equal the receiver must check if the received CRC is equal to the previous CRC. If the CRCs are equal, the packet is defined as equal to the previous packet and is discarded. Refer to the right flow chart in Figure 8.
Figure 8. PID generation/detection

6.4.4.4   Automatic packet disassembly

After the packet is validated, Enhanced ShockBurst™ disassembles the packet and loads the payload into the RX FIFO, and asserts the RX_DR IRQ.

6.4.5   Automatic packet transaction handling

Enhanced ShockBurst™ features two functions for automatic packet transaction handling; auto acknowledgement and auto re-transmit.

6.4.5.1 Auto acknowledgement

Auto acknowledgment is a function that automatically transmits an ACK packet to the PTX after it has received and validated a packet. The auto acknowledgement feature is enabled by setting the EN_AA register. This reduces cost and average current consumption.

> **Note:** If the received packet has the NO_ACK flag set, the auto acknowledgement is not executed.

An ACK packet can contain an optional payload from PRX to PTX. In order to use this feature, the dynamic payload length feature must be enabled. The on-chip MCU on the PRX side has to upload the payload by clocking it into the TX FIFO by using the W_ACK_PAYLOAD command. The payload is pending in the TX FIFO (PRX) until a new packet is received from the PTX. The RF Transceiver can have three ACK packet payloads pending in the TX FIFO (PRX) at the same time.
Figure 9. TX FIFO (PRX) with pending payloads

Figure 9. shows how the TX FIFO (PRX) is operated when handling pending ACK packet payloads. From the on-chip MCU the payload is clocked in with the W_ACK_PAYLOAD command. The address decoder and buffer controller ensure that the payload is stored in a vacant slot in the TX FIFO (PRX). When a packet is received, the address decoder and buffer controller are notified with the PTX address. This ensures that the right payload is presented to the ACK generator.

If the TX FIFO (PRX) contains more than one payload to a PTX, payloads are handled using the first in – first out principle. The TX FIFO (PRX) is blocked if all pending payloads are addressed to a PTX where the link is lost. In this case, the on-chip MCU can flush the TX FIFO (PRX) by using the FLUSH_TX command.

In order to enable Auto Acknowledgement with payload the EN_ACK_PAY bit in the FEATURE register must be set.

6.4.5.2 Auto Retransmission (ART)

The auto retransmission is a function that retransmits a packet if an ACK packet is not received. It is used at the PTX side in an auto acknowledgement system. You can set up the number of times a packet is allowed to be retransmitted if a packet is not acknowledged with the ARC bits in the SETUP_RETR register. PTX enters RX mode and waits for an ACK packet each time a packet is transmitted. The time period the PTX is in RX mode is based on the following conditions:

- Auto Retransmit Delay (ARD) elapsed
- No address match within 250µs
- After received packet (CRC correct or not) if address match within 250µs

The RF Transceiver asserts the TX_DS IRQ when the ACK packet is received.

The RF Transceiver enters standby-I mode if there is no more untransmitted data in the TX FIFO and the `rfce` bit in the `RFCON` register is low. If the ACK packet is not received, the RF Transceiver goes back to TX mode after a delay defined by ARD and retransmits the data. This continues until acknowledgment is received, or the maximum number of retransmits is reached. Set `PWR_UP` =0 to abort auto retransmission. Two packet loss counters are incremented each time a packet is lost, ARC_CNT and PLOS_CNT in the `OBSERVE_TX` register. The ARC_CNT counts the number of retransmissions for the current transaction. The PLOS_CNT counts the total number of retransmissions since the last channel change. You reset ARC_CNT by initiating a new transaction. You reset PLOS_CNT by writing to the `RF_CH` register. It is possible to use the information in the `OBSERVE_TX` register to make an overall assessment of the channel quality.

The ARD defines the time from the end of a transmitted packet to when a retransmit starts on the PTX side. ARD is set in SETUP_RETR register in steps of 250µs. A retransmit is made if no ACK packet is received by the PTX.

There is a restriction for the length of ARD when using ACK packets with payload. The ARD time must never be shorter than the sum of the startup time and the time on-air for the ACK packet.

For 1Mbps data rate and 5 byte address; 5 byte is maximum ACK packet payload length for ARD=250µs (reset value).

For 2Mbps data rate and 5 byte address; 15 byte is maximum ACK packet payload length for ARD=250µs (reset value).

ARD=500µs is long enough for any payload length.

As an alternative to Auto Retransmit it is possible to manually set the RF Transceiver to retransmit a packet a number of times. This is done by the `REUSE_TX_PL` command. The MCU must initiate each transmission of the packet with the `rfce` bit in the `RFCON` register after this command is used.

6.4.6   Enhanced Shockburst™ flowcharts

This section contains flowcharts showing PTX and PRX operation in Enhanced ShockBurst™.

6.4.6.1   PTX operation

The flowchart in Figure 10. shows how a RF Transceiver configured as a PTX behaves after entering standby-I mode.
Note: ShockBurst™ operation is outlined with a dashed square.

Figure 10. PTX operations in Enhanced ShockBurst™

Activate PTX mode by enabling the `rfce` bit in the `RFCON` register. If there is a packet present in the TX FIFO the RF Transceiver enters TX mode and transmits the packet. If Auto Retransmit is enabled, the state machine checks if the `NO_ACK` flag is set. If it is not set, the RF Transceiver enters RX mode to receive an ACK packet. If the received ACK packet is empty, only the `TX_DS` IRQ is asserted. If the ACK packet contains a payload, both `TX_DS` IRQ and `RX_DR` IRQ are asserted simultaneously before the RF Transceiver returns to standby-I mode.

If the ACK packet is not received before time-out occurs, the RF Transceiver returns to standby-I mode. It stays in standby-I mode until the ARD has elapsed. If the number of retransmits has not reached the ARC, the RF Transceiver enters TX mode and transmits the last packet once more.

While executing the Auto Retransmit feature, the number of retransmits can reach the maximum number defined in `ARC`. If this happens, the RF Transceiver asserts the `MAX_RT` IRQ and returns to standby-I mode.

If the `rfce` is high and the TX FIFO is empty, the RF Transceiver enters Standby-II mode.

6.4.6.2 PRX operation

The flowchart in [Figure 11.](#) shows how a RF Transceiver configured as a PRX behaves after entering standby-I mode.
Note: ShockBurst™ operation is outlined with a dashed square.

Figure 11. PRX operations in Enhanced ShockBurst™

Activate PRX mode by setting the `rfce` bit in the `RFCON` register high. The RF Transceiver enters RX mode and starts searching for packets. If a packet is received and Auto Acknowledgement is enabled the RF Transceiver decides if it is a new packet or a copy of a previously received packet. If it is a new packet,

the payload is made available in the RX FIFO and the `RX_DR` IRQ is asserted. If the last received packet from the transmitter is acknowledged with an ACK packet with payload, the `TX_DS` IRQ indicates that the PTX received the ACK packet with payload. If the `No_ACK` flag is not set in the received packet, the PRX enters TX mode. If there is a pending payload in the TX FIFO it is attached to the ACK packet. After the ACK packet is transmitted, the RF Transceiver returns to RX mode.

A copy of a previously received packet might be received if the ACK packet is lost. In this case, the PRX discards the received packet and transmits an ACK packet before it returns to RX mode.

6.4.7   Multiceiver™

Multiceiver™ is a feature used in RX mode that contains a set of six parallel data pipes with unique addresses. A data pipe is a logical channel in the physical RF channel. Each data pipe has its own physical address decoding in the RF Transceiver.

Figure 12. PRX using Multiceiver™

The RF Transceiver configured as a PRX (primary receiver) can receive data addressed to six different data pipes in one frequency channel as shown in Figure 12. Each data pipe has its own unique address and can be configured for individual behavior.

Up to six RF Transceivers configured as a PTX can communicate with one RF Transceiver configured as a PRX. All data pipe addresses are searched for simultaneously. Only one data pipe can receive a packet at a time. All data pipes can perform Enhanced ShockBurst™ functionality.

The following settings are common to all data pipes:

- CRC enabled/disabled (CRC always enabled when Enhanced ShockBurst™ is enabled)
- CRC encoding scheme
- RX address width
- Frequency channel
- Air data rate
- LNA gain

The data pipes are enabled with the bits in the EN_RXADDR register. By default only data pipe 0 and 1 are enabled. Each data pipe address is configured in the RX_ADDR_PX registers.

Note: Always ensure that none of the data pipes have the same address.

Each pipe can have up to 5 byte configurable address. Data pipe 0 has a unique 5 byte address. Data pipes 1-5 share the 4 most significant address bytes. The LSByte must be unique for all six pipes. Figure 13. is an example of how data pipes 0-5 are addressed.

	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0
Data pipe 0 (RX_ADDR_P0)	0xE7	0xD3	0xF0	0x35	0x77
Data pipe 1 (RX_ADDR_P1)	0xC2	0xC2	0xC2	0xC2	**0xC2**
Data pipe 2 (RX_ADDR_P2)	0xC2	0xC2	0xC2	0xC2	**0xC3**
Data pipe 3 (RX_ADDR_P3)	0xC2	0xC2	0xC2	0xC2	**0xC4**
Data pipe 4 (RX_ADDR_P4)	0xC2	0xC2	0xC2	0xC2	**0xC5**
Data pipe 5 (RX_ADDR_P5)	0xC2	0xC2	0xC2	0xC2	**0xC6**

Figure 13. Addressing data pipes 0-5

The PRX, using Multiceiver™ and Enhanced ShockBurst™, receives packets from more than one PTX. To ensure that the ACK packet from the PRX is transmitted to the correct PTX, the PRX takes the data pipe address where it received the packet and uses it as the TX address when transmitting the ACK packet. Figure 14. is an example of an address configuration for the PRX and PTX. On the PRX the RX_ADDR_Pn, defined as the pipe address, must be unique. On the PTX, the TX_ADDR must be the same as the RX_ADDR_P0 and also as the pipe address for the designated pipe.

Addr Data Pipe 0 (RX_ADDR_P0): 0x7878787878
Addr Data Pipe 1 (RX_ADDR_P1): 0xB3B4B5B6**F1**
Addr Data Pipe 2 (RX_ADDR_P2): 0xB3B4B5B6**CD**
Addr Data Pipe 3 (RX_ADDR_P3): 0xB3B4B5B6**A3**
Addr Data Pipe 4 (RX_ADDR_P4): 0xB3B4B5B6**0F**
Addr Data Pipe 5 (RX_ADDR_P5): 0xB3B4B5B6**05**
Figure 14. Example of data pipe addressing in Multiceiver™

Only when a data pipe receives a complete packet can other data pipes begin to receive data. When multiple PTXs are transmitting to a PRX, the ARD can be used to skew the auto retransmission so that they only block each other once.

6.4.8 Enhanced Shockburst™ timing

This section describes the timing sequence of Enhanced ShockBurst™ and how all modes are initiated and operated. The Enhanced ShockBurst™ timing is controlled through the Data and Control interface. The RF Transceiver can be set to static modes or autonomous modes where the internal state machine controls the events. Each autonomous mode/sequence ends with an interrupt at the RFIRQ. All the interrupts are indicated as IRQ events in the timing diagrams.

1 IRQ if No Ack is on.

T_{IRQ} = 8.2µs @ 1Mbps, T_{IRQ} = 6.0µs @ 2Mbps, $T_{stdby2a}$ = 130us
Figure 15. Transmitting one packet with NO_ACK on

The following equations calculate various timing measurements:

Symbol	Description	Equation
T_{OA}	Time on-air	$T_{OA} = \dfrac{packet\,length}{air\,data\,rate} = \dfrac{8\left[bit/byte\right] \cdot \left(\underset{preamble}{1\,[byte]} + \underset{address}{3,4\,or\,5\,[bytes]} + \underset{payload}{N\,[bytes]} + \underset{CRC}{1\,or\,2\,[bytes]}\right) + \underset{packet\,control\,field}{9\,[bit]}}{air\,data\,rate\,\left[bit/s\right]}$
T_{ACK}	Time on-air Ack	$T_{ACK} = \dfrac{packet\,length}{air\,data\,rate} = \dfrac{8\left[bit/byte\right] \cdot \left(\underset{preamble}{1\,[byte]} + \underset{address}{3,4\,or\,5\,[bytes]} + \underset{payload}{N\,[bytes]} + \underset{CRC}{1\,or\,2\,[bytes]}\right) + \underset{packet\,control\,field}{9\,[bit]}}{air\,data\,rate\,\left[bit/s\right]}$
T_{UL}	Time Upload	$T_{UL} = \dfrac{payload\,length}{SPI\,data\,rate} = \dfrac{8\left[bit/byte\right] \cdot \underset{payload}{N\,[bytes]}}{SPI\,data\,rate\,\left[bit/s\right]}$
T_{ESB}	Time Enhanced Shock-Burst™ cycle	$T_{ESB} = T_{UL} + 2 \cdot T_{stby2a} + T_{OA} + T_{ACK} + T_{IRQ}$

Table 16. Timing equations
Figure 16. Timing of Enhanced ShockBurst™ for one packet upload (2Mbps)

In Figure 16. shows the transmission and acknowledgement of a packet. The PRX device is turned into RX mode (CE=1), and the PTX device is set to TX mode (CE=1 for minimum 10µs). After 130µs the transmission starts and finishes after the elapse of TOA.

When the transmission ends the PTX device automatically switches to RX mode to wait for the ACK packet from the PRX device. After the PTX device receives the ACK packet it responds with an interrupt to the MCU. When the PRX device receives the packet it responds with an interrupt to the MCU.

6.4.9   Enhanced Shockburst™ transaction diagram

This section describes several scenarios for the Enhanced ShockBurst™ automatic transaction handling. The call outs in this section's figures indicate the IRQs and other events. For MCU activity the event may be placed at a different time frame.

> **Note:** The figures in this section indicate the earliest possible download (DL) of the packet to the MCU and the latest possible upload (UL) of payload to the transmitter.

6.4.9.1   Single transaction with ACK packet and interrupts

Figure 17. shows the basic auto acknowledgement. After the packet is transmitted by the PTX and received by the PRX the ACK packet is transmitted from the PRX to the PTX. The RX_DR IRQ is asserted

after the packet is received by the PRX, whereas the `TX_DS IRQ` is asserted when the packet is acknowledged and the ACK packet is received by the PTX.

1 Radio Turn Around Delay
Figure 17. TX/RX cycles with ACK and the according interrupts

6.4.9.2 Single transaction with a lost packet

Figure 18. is a scenario where a retransmission is needed due to loss of the first packet transmit. After the packet is transmitted, the PTX enters RX mode to receive the ACK packet. After the first transmission, the PTX waits a specified time for the ACK packet, if it is not in the specific time slot the PTX retransmits the packet as shown in Figure 18.

1 Radio Turn Around Delay
Figure 18. TX/RX cycles with ACK and the according interrupts when the first packet transmit fails

When an address is detected the PTX stays in RX mode until the packet is received. When the retransmitted packet is received by the PRX (see Figure 18.), the `RX_DR IRQ` is asserted and an ACK is transmitted back to the PTX. When the ACK is received by the PTX, the `TX_DS IRQ` is asserted.

6.4.9.3 Single transaction with a lost ACK packet

Figure 19. is a scenario where a retransmission is needed after a loss of the ACK packet. The corresponding interrupts are also indicated.

1 Radio Turn Around Delay
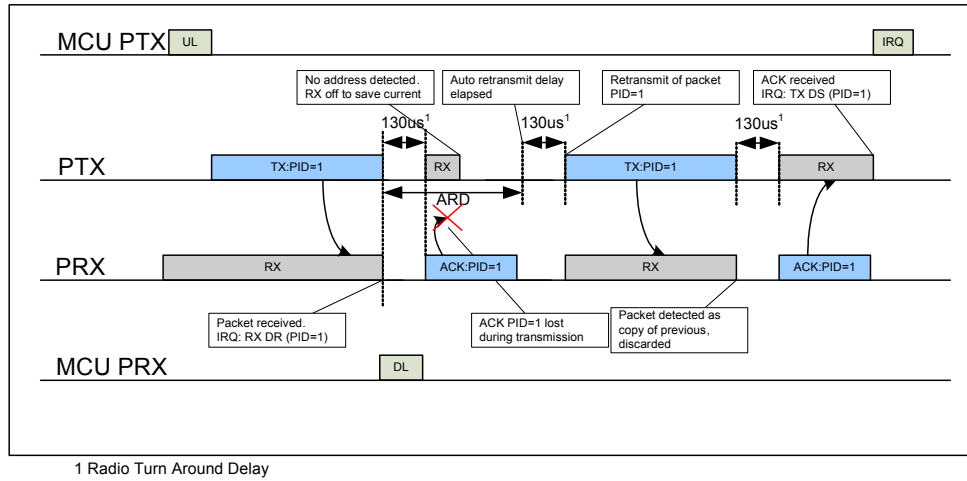

Figure 19. TX/RX cycles with ACK and the according interrupts when the ACK packet fails

6.4.9.4 Single transaction with ACK payload packet

Figure 20. is a scenario of the basic auto acknowledgement with payload. After the packet is transmitted by the PTX and received by the PRX the ACK packet with payload is transmitted from the PRX to the PTX. The RX_DR IRQ is asserted after the packet is received by the PRX, whereas on the PTX side the TX_DS IRQ is asserted when the ACK packet is received by the PTX. On the PRX side, the TX_DS IRQ for the ACK packet payload is asserted after a new packet from PTX is received. The position of the IRQ in Figure 20. shows where the MCU can respond to the interrupt.

1 Radio Turn Around Delay
2 Uploading Paylod for Ack Packet
3 Delay defined by MCU on PTX side, ≥ 130us
Figure 20. TX/RX cycles with ACK Payload and the according interrupts

6.4.9.5 Single transaction with ACK payload packet and lost packet

Figure 21. is a scenario where the first packet is lost and a retransmission is needed before the `RX_DR` IRQ on the PRX side is asserted. For the PTX both the `TX_DS` and `RX_DR` IRQ are asserted after the ACK packet is received. After the second packet (PID=2) is received on the PRX side both the `RX_DR` (PID=2) and `TX_DS` (ACK packet payload) IRQ are asserted.

1 Radio Turn Around Delay
2 Uploading Paylod for Ack Packet
3 Delay defined by MCU on PTX side, ≥ 130us
Figure 21. TX/RX cycles and the according interrupts when the packet transmission fails

6.4.9.6 Two transactions with ACK payload packet and the first ACK packet lost

1 Radio Turn Around Delay
2 Uploading Paylod for Ack Packet
3 Delay defined by MCU on PTX side, ≥ 130us
Figure 22. TX/RX cycles with ACK Payload and the according interrupts when the ACK packet fails

In Figure 22. the ACK packet is lost and a retransmission is needed before the `TX_DS` IRQ is asserted, but the `RX_DR` IRQ is asserted immediately. The retransmission of the packet (PID=1) results in a discarded packet. For the PTX both the `TX_DS` and `RX_DR` IRQ are asserted after the second transmission of ACK, which is received. After the second packet (PID=2) is received on the PRX, the `RX_DR` (PID=2) and `TX_DS` (ACK1PAY) IRQ are asserted. The callouts explain the different events and interrupts.

6.4.9.7   Two transactions where max retransmissions are reached

1 Radio Turn Around Delay
2 Uploading Payload for Ack Packet
3 Delay defined by MCU on PTX side, ≥ 130us
Figure 23. TX/RX cycles with ACK Payload and the according interrupts when the transmission fails. ARC is set to 2.

If the auto retransmit counter (ARC_CNT) exceeds the programmed maximum limit (ARC), the MAX_RT IRQ is asserted. In Figure 23. the packet transmission ends with a MAX_RT IRQ. The payload in TX FIFO is not removed and the MCU decides the next step in the protocol. A toggle of the rfce starts a new sequence of transmitting the same packet. The payload can be removed from the TX FIFO using the FLUSH_TX command.

6.4.10   Compatibility with ShockBurst™

The nRF24LU1 can have the Enhanced ShockBurst™ feature disabled in order to be backward compatible with the nRF2401A, nRF2402, nRF24E1and nRF24E2.

Disabling the Enhanced ShockBurst™ features is done by setting register EN_AA=0x00 and the ARC = 0.

In addition, the nRF24LU1 air data rate must be set to 1Mbps.

6.4.10.1   ShockBurst™ packet format

This section describes the ShockBurst™ packet format.

Preamble 1 byte	Address 3-5 byte	Payload 1 - 32 byte	CRC 1-2 byte

Note: MSB to the left.

Figure 24. A ShockBurst™ packet compatible with nRF2401/nRF2402/nRF24E1/nRF24E2 devices.

The ShockBurst™ packet format has a preamble, address, payload and CRC field that is the same as in the Enhanced ShockBurst™ packet format described in section 6.4.3 on page 34.

The differences between the ShockBurst™ packet and the Enhanced ShockBurst™ packet are:

- The 9 bit Packet Control Field is not present in the ShockBurst™ packet format.
- The CRC is optional in the ShockBurst™ packet format and is controlled by the EN_CRC bit in the CONFIG register.

6.5 Data and control interface

The data and control interface gives you access to all the features in the RF Transceiver. Compared to the standalone component SFR registers are used instead of port pins. Otherwise the interface is identical to the standalone nRF24L01 chip.

6.5.1 SFR registers

The MCU uses an internal SPI to communicate with the RF Transceiver. This SPI is controlled by the SFR registers shown in the tables below.

Address	Reset value	Bit	Name	R/W	Function
0xE5	0x00		data	RW	SPI data input/output

Table 17. RFDAT register

Address	Reset value	Bit	Name	R/W	Function
0xE6	0x00	7:5	-		Must be zero
		4	ss	RW	SPI enable: 00: disable, 01: enable
		3:0	rfctl	RW	Divider factor from MCU clock (Cclk) to SPI clock frequency 000X: 1/2 of Cclk frequency 0010: 1/4 of Cclk frequency 0011: 1/8 of Cclk frequency 0100: 1/16 of Cclk frequency 0101: 1/32 of Cclk frequency other: 1/64 of Cclk frequency

Table 18. RFCTL register

Address	Reset value	Bit	Name	R/W	Function
0x90	0x02	7:3	-		Reserved
		2	rfcken	RW	RF Clock Enable (16MHz)
		1	rfcsn	RW	RF SPI CSN 0: enabled 1: disabled
		0	rfce	RW	RF CE 1: enabled 0: disabled

Table 19. RFCON register

6.5.2 Command set

The SPI commands are shown in Table 20. Every new command must be started by writing 0 to rfcsn in the `RFCON` register.

The SPI command is transferred to RF Transceiver by writing the command to the `RFDAT` register. After the first transfer the RF Transceiver's `STATUS` register can be read from `RFDAT` when the transfer is completed.

The serial shifting SPI commands is in the following format:

<Command word: one byte>

<Data bytes: LSByte to MSByte>

Command name	Command word (binary)	# Data bytes	Operation
R_REGISTER	000A AAAA	1 to 5 LSByte first	Read command and status registers. AAAAA = 5 bit Register Map Address
W_REGISTER	001A AAAA	1 to 5 LSByte first	Write command and status registers. AAAAA = 5 bit Register Map Address Executable in power down or standby modes only.
R_RX_PAYLOAD	0110 0001	1 to 32 LSByte first	Read RX-payload: 1 – 32 bytes. A read operation always starts at byte 0. Payload is deleted from FIFO after it is read. Used in RX mode.
W_TX_PAYLOAD	1010 0000	1 to 32 LSByte first	Write TX-payload: 1 – 32 bytes. A write operation always starts at byte 0 used in TX payload.
FLUSH_TX	1110 0001	0	Flush TX FIFO, used in TX mode.
FLUSH_RX	1110 0010	0	Flush RX FIFO, used in RX mode Should not be executed during transmission of acknowledge, that is, acknowledge package will not be completed.
REUSE_TX_PL	1110 0011	0	Used for a PTX device Pulse the `rfce` high for at least 10µs to Reuse last transmitted payload. TX payload reuse is active until `W_TX_PAYLOAD` or `FLUSH_TX` is executed.

Command name	Command word (binary)	# Data bytes	Operation
ACTIVATE	0101 0000	1	This write command followed by data 0x73 activates the following features: • R_RX_PL_WID • W_ACK_PAYLOAD • W_TX_PAYLOAD_NOACK A new ACTIVATE command with the same data deactivates them again. This is executable in power down or stand by modes only. The R_RX_PL_WID, W_ACK_PAYLOAD, and W_TX_PAYLOAD_NOACK features registers are initially in a deactivated state; a write has no effect, a read only results in zeros on MISO. To activate these registers, use the ACTIVATE command followed by data 0x73. Then they can be accessed as any other register in RF Transceiver. Use the same command and data to deactivate the registers again.
R_RX_PL_WID[a]	0110 0000	1	Read RX-payload width for the top R_RX_PAYLOAD in the RX FIFO.
W_ACK_PAYLOAD[a]	1010 1PPP	1 to 32 LSByte first	Used in RX mode. Write Payload to be transmitted together with ACK packet on PIPE PPP. (PPP valid in the range from 000 to 101). Maximum three ACK packet payloads can be pending. Payloads with same PPP are handled using first in - first out principle. Write payload: 1– 32 bytes. A write operation always starts at byte 0.
W_TX_PAYLOAD_NOACK[a]	1011 0000	1 to 32 LSByte first	Used in TX mode. Disables AUTOACK on this specific packet.
NOP	1111 1111	0	No Operation. Might be used to read the STATUS register

a. To activate this feature use the ACTIVATE SPI command followed by data 0x73. The corresponding bits in the FEATURE register shown in Table 21. on page 61 have to be set.

Table 20. Command set for the RF Transceiver SPI

The W_REGISTER and R_REGISTER commands can operate on single or multi-byte registers. When accessing multi-byte registers you read or write to the LSByte first. You can terminate the writing before all bytes in a multi-byte register are written, leaving unwritten MSBytes unchanged. For example, the LSByte of RX_ADDR_P0 can be modified by writing only one byte to the RX_ADDR_P0 register. The content of the status register is always read to RFDAT after changing the rfcsn value from 1 to 0.

6.5.3   Data FIFO

The data FIFOs are used to store payload that is transmitted (TX FIFO) or payload that is received and ready to be clocked out (RX FIFO). The FIFOs are accessible in both PTX mode and PRX mode.

The following FIFOs are present in RF Transceiver:

- TX three level, 32 byte FIFO
- RX three level, 32 byte FIFO

Both FIFOs have a controller and are accessible through the SPI by using dedicated SPI commands. A TX FIFO in PRX can store payload for ACK packets to three different PTX devices. If the TX FIFO contains more than one payload to a pipe, payloads are handled using the first in - first out principle. The TX FIFO in a PRX is blocked if all pending payloads are addressed to pipes where the link to the PTX is lost. In this case, the MCU can flush the TX FIFO by using the FLUSH_TX command.

The RX FIFO in PRX may contain payload from up to three different PTX devices.

A TX FIFO in PTX can have up to three payloads stored.

The TX FIFO can be written to by three commands, W_TX_PAYLOAD and W_TX_PAYLOAD_NO_ACK in PTX mode and W_ACK_PAYLOAD in PRX mode. All three commands give access to the TX_PLD register.

The RX FIFO can be read by the command R_RX_PAYLOAD in both PTX and PRX mode. This command gives access to the RX_PLD register.

The payload in TX FIFO in a PTX is NOT removed if the MAX_RT IRQ is asserted. Figure 25. is a block diagram of the TX FIFO and the RX FIFO.
Figure 25. FIFO block diagram

In the FIFO_STATUS register it is possible to read if the TX and RX FIFO is full or empty. The TX_REUSE bit is also available in the FIFO_STATUS register. TX_REUSE is set by the SPI command REUSE_TX_PL, and is reset by the SPI commands W_TX_PAYLOAD or FLUSH TX.

6.5.4 Interrupt

The RF Transceiver can send interrupts to the MCU. The interrupt is activated when `TX_DS`, `RX_DR` or `MAX_RT` is set high in the `STATUS` register. When the MCU writes '1' to the IRQ source bit in the `STATUS` register, the `rfirq` bit becomes inactive. The interrupt mask part of the `CONFIG` register is used to mask out the interrupt sources that are allowed to set the `rfirq` low. By setting one of the MASK bits high, the corresponding interrupt source is disabled. By default all interrupt sources are enabled.

> **Note:** The 3 bit pipe information in the STATUS register is updated during the `rfirq` high to low transition. If the STATUS register is read during an `rfirq` high to low transition, the pipe information is unreliable.

6.6 Register Map

By accessing the register map through the SPI you can configure and control the radio (using read and write commands).

6.6.1 Register map table

All undefined bits in the table below are redundant. They are read out as '0'.

> **Note:** Addresses 18 to 1B are reserved for test purposes, altering them will make the chip malfunction.

Address (Hex)	Mnemonic	Bit	Reset Value	Type	Description
00	`CONFIG`				Configuration Register
	Reserved	7	0	R/W	Only '0' allowed
	`MASK_RX_DR`	6	0	R/W	Mask interrupt caused by `RX_DR` 1: Interrupt not reflected on `rfirq` 0: Reflect RX_DR as active low interrupt on the `rfirq`
	`MASK_TX_DS`	5	0	R/W	Mask interrupt caused by `TX_DS` 1: Interrupt not reflected on the `rfirq` 0: Reflect `TX_DS` as active low interrupt on the `rfirq`
	`MASK_MAX_RT`	4	0	R/W	Mask interrupt caused by `MAX_RT` 1: Interrupt not reflected on the `rfirq` 0: Reflect `MAX_RT` as active low interrupt on the `rfirq`
	`EN_CRC`	3	1	R/W	Enable CRC. Forced high if one of the bits in the `EN_AA` is high
	`CRCO`	2	0	R/W	CRC encoding scheme '0' - 1 byte '1' – 2 bytes
	`PWR_UP`	1	0	R/W	1: POWER UP, 0:POWER DOWN
	`PRIM_RX`	0	0	R/W	RX/TX control 1: PRX, 0: PTX
01	`EN_AA` Enhanced ShockBurst™				Enable 'Auto Acknowledgment' Function Disable this functionality to be compatible with nRF2401.

Address (Hex)	Mnemonic	Bit	Reset Value	Type	Description
	Reserved	7:6	00	R/W	Only '00' allowed
	ENAA_P5	5	1	R/W	Enable auto acknowledgement data pipe 5
	ENAA_P4	4	1	R/W	Enable auto acknowledgement data pipe 4
	ENAA_P3	3	1	R/W	Enable auto acknowledgement data pipe 3
	ENAA_P2	2	1	R/W	Enable auto acknowledgement data pipe 2
	ENAA_P1	1	1	R/W	Enable auto acknowledgement data pipe 1
	ENAA_P0	0	1	R/W	Enable auto acknowledgement data pipe 0
02	EN_RXADDR				Enabled RX Addresses
	Reserved	7:6	00	R/W	Only '00' allowed
	ERX_P5	5	0	R/W	Enable data pipe 5.
	ERX_P4	4	0	R/W	Enable data pipe 4.
	ERX_P3	3	0	R/W	Enable data pipe 3.
	ERX_P2	2	0	R/W	Enable data pipe 2.
	ERX_P1	1	1	R/W	Enable data pipe 1.
	ERX_P0	0	1	R/W	Enable data pipe 0.
03	SETUP_AW				Setup of Address Widths (common for all data pipes)
	Reserved	7:2	000000	R/W	Only '000000' allowed
	AW	1:0	11	R/W	RX/TX Address field width '00' - Illegal '01' - 3 bytes '10' - 4 bytes '11' – 5 bytes LSByte is used if address width is below 5 bytes
04	SETUP_RETR				Setup of Automatic Retransmission
	ARD	7:4	0000	R/W	Auto Retransmit Delay '0000' – Wait 250µS '0001' – Wait 500µS '0010' – Wait 750µS …….. '1111' – Wait 4000µS (Delay defined from end of transmission to start of next transmission)[a]
	ARC	3:0	0011	R/W	Auto Retransmit Count '0000' –Re-Transmit disabled '0001' – Up to 1 Re-Transmit on fail of AA …… '1111' – Up to 15 Re-Transmit on fail of AA
05	RF_CH				RF Channel
	Reserved	7	0	R/W	Only '0' allowed
	RF_CH	6:0	0000010	R/W	Sets the frequency channel RF Transceiver operates on
06	RF_SETUP				RF Setup Register
	Reserved	7:5	000	R/W	Only '000' allowed
	PLL_LOCK	4	0	R/W	Force PLL lock signal. Only used in test

Address (Hex)	Mnemonic	Bit	Reset Value	Type	Description
	RF_DR	3	1	R/W	Air Data Rate '0' – 1Mbps '1' – 2Mbps
	RF_PWR	2:1	11	R/W	Set RF output power in TX mode '00' – -18dBm '01' – -12dBm '10' – -6dBm '11' – 0dBm
	LNA_HCURR	0	1	R/W	Setup LNA gain
07	STATUS				Status Register (In parallel to the SPI command word applied on the MOSI pin, the STATUS register is shifted serially out on the MISO pin)
	Reserved	7	0	R/W	Only '0' allowed
	RX_DR	6	0	R/W	Data Ready RX FIFO interrupt. Asserted when new data arrives RX FIFO[b]. Write 1 to clear bit.
	TX_DS	5	0	R/W	Data Sent TX FIFO interrupt. Asserted when packet transmitted on TX. If EN_AA (see page 56) is activated, this bit is set high only when ACK is received. Write 1 to clear bit.
	MAX_RT	4	0	R/W	Maximum number of TX retransmits interrupt Write 1 to clear bit. If MAX_RT is asserted it must be cleared to enable further communication.
	RX_P_NO	3:1	111	R	Data pipe number for the payload available for reading from RX_FIFO 000-101: Data Pipe Number 110: Not Used 111: RX FIFO Empty
	TX_FULL	0	0	R	TX FIFO full flag. 1: TX FIFO full. 0: Available locations in TX FIFO.
08	OBSERVE_TX				Transmit observe register
	PLOS_CNT	7:4	0	R	Count lost packets. The counter is overflow protected to 15, and discontinues at max until reset. The counter is reset by writing to RF_CH.
	ARC_CNT	3:0	0	R	Count retransmitted packets. The counter is reset when transmission of a new packet starts.
09	CD				
	Reserved	7:1	000000	R	
	CD	0	0	R	Carrier Detect.
0A	RX_ADDR_P0	39:0	0xE7E7E7E7E7	R/W	Receive address data pipe 0. 5 Bytes maximum length. (LSByte is written first. Write the number of bytes defined by SETUP_AW)
0B	RX_ADDR_P1	39:0	0xC2C2C2C2C2	R/W	Receive address data pipe 1. 5 Bytes maximum length. (LSByte is written first. Write the number of bytes defined by SETUP_AW)

Address (Hex)	Mnemonic	Bit	Reset Value	Type	Description
0C	RX_ADDR_P2	7:0	0xC3	R/W	Receive address data pipe 2. Only LSB. MSBytes is equal to RX_ADDR_P1[39:8]
0D	RX_ADDR_P3	7:0	0xC4	R/W	Receive address data pipe 3. Only LSB. MSBytes is equal to RX_ADDR_P1[39:8]
0E	RX_ADDR_P4	7:0	0xC5	R/W	Receive address data pipe 4. Only LSB. MSBytes is equal to RX_ADDR_P1[39:8]
0F	RX_ADDR_P5	7:0	0xC6	R/W	Receive address data pipe 5. Only LSB. MSBytes is equal to RX_ADDR_P1[39:8]
10	TX_ADDR	39:0	0xE7E7E7E7E7	R/W	Transmit address. Used for a PTX device only. (LSByte is written first) Set RX_ADDR_P0 equal to this address to handle automatic acknowledge if this is a PTX device with Enhanced ShockBurst™ enabled.
11	RX_PW_P0				
	Reserved	7:6	00	R/W	Only '00' allowed
	RX_PW_P0	5:0	0	R/W	Number of bytes in RX payload in data pipe 0 (1 to 32 bytes). 0 Pipe not used 1 = 1 byte … 32 = 32 bytes
12	RX_PW_P1				
	Reserved	7:6	00	R/W	Only '00' allowed
	RX_PW_P1	5:0	0	R/W	Number of bytes in RX payload in data pipe 1 (1 to 32 bytes). 0 Pipe not used 1 = 1 byte … 32 = 32 bytes
13	RX_PW_P2				
	Reserved	7:6	00	R/W	Only '00' allowed
	RX_PW_P2	5:0	0	R/W	Number of bytes in RX payload in data pipe 2 (1 to 32 bytes). 0 Pipe not used 1 = 1 byte … 32 = 32 bytes
14	RX_PW_P3				
	Reserved	7:6	00	R/W	Only '00' allowed
	RX_PW_P3	5:0	0	R/W	Number of bytes in RX payload in data pipe 3 (1 to 32 bytes). 0 Pipe not used 1 = 1 byte … 32 = 32 bytes

Address (Hex)	Mnemonic	Bit	Reset Value	Type	Description
15	RX_PW_P4				
	Reserved	7:6	00	R/W	Only '00' allowed
	RX_PW_P4	5:0	0	R/W	Number of bytes in RX payload in data pipe 4 (1 to 32 bytes). 0 Pipe not used 1 = 1 byte … 32 = 32 bytes
16	RX_PW_P5				
	Reserved	7:6	00	R/W	Only '00' allowed
	RX_PW_P5	5:0	0	R/W	Number of bytes in RX payload in data pipe 5 (1 to 32 bytes). 0 Pipe not used 1 = 1 byte … 32 = 32 bytes
17	FIFO_STATUS				FIFO Status Register
	Reserved	7	0	R/W	Only '0' allowed
	TX_REUSE	6	0	R	Used for a PTX device. Pulse the rfce high for at least 10µs to Reuse last transmitted payload. TX payload reuse is active until W_TX_PAYLOAD or FLUSH_TX is executed.
	TX_FULL	5	0	R	TX FIFO full flag. 1: TX FIFO full. 0: Available locations in TX FIFO.
	TX_EMPTY	4	1	R	TX FIFO empty flag. 1: TX FIFO empty. 0: Data in TX FIFO.
	Reserved	3:2	00	R/W	Only '00' allowed
	RX_FULL	1	0	R	RX FIFO full flag. 1: RX FIFO full. 0: Available locations in RX FIFO.
	RX_EMPTY	0	1	R	RX FIFO empty flag. 1: RX FIFO empty. 0: Data in RX FIFO.
N/A	ACK_PLD[c]	255:0	X	W	Written by separate SPI command ACK packet payload to data pipe number PPP given in SPI command Used in RX mode only Maximum three ACK packet payloads can be pending. Payloads with same PPP are handled first in first out.
N/A	TX_PLD	255:0	X	W	Written by separate SPI command TX data payload register 1 - 32 bytes. This register is implemented as a FIFO with three levels. Used in TX mode only

Address (Hex)	Mnemonic	Bit	Reset Value	Type	Description
N/A	RX_PLD	255:0	X	R	Read by separate SPI command RX data payload register. 1 - 32 bytes. This register is implemented as a FIFO with three levels. All RX channels share the same FIFO
1C	DYNPD[c]				Enable dynamic payload length
	Reserved	7:6	0	R/W	Only '00' allowed
	DPL_P5	5	0	R/W	Enable dynamic payload length data pipe 5. (Requires EN_DPL and ENAA_P5)
	DPL_P4	4	0	R/W	Enable dyn. payload length data pipe 4. (Requires EN_DPL and ENAA_P4)
	DPL_P3	3	0	R/W	Enable dyn. payload length data pipe 3. (Requires EN_DPL and ENAA_P3)
	DPL_P2	2	0	R/W	Enable dyn. payload length data pipe 2. (Requires EN_DPL and ENAA_P2)
	DPL_P1	1	0	R/W	Enable dyn. payload length data pipe 1. (Requires EN_DPL and ENAA_P1)
	DPL_P0	0	0	R/W	Enable dyn. payload length data pipe 0. (Requires EN_DPL and ENAA_P0)
1D	FEATURE[c]			R/W	Feature Register
	Reserved	7:3	0	R/W	Only '00000' allowed
	EN_DPL	2	0	R/W	Enables Dynamic Payload Length
	EN_ACK_PAY[d]	1	0	R/W	Enables Payload with ACK
	EN_DYN_ACK	0	0	R/W	Enables the W_TX_PAYLOAD_NOACK command

a. This is the time the PTX is waiting for an ACK packet before a retransmit is made. The PTX is in RX mode for a minimum of 250µS, but it stays in RX mode to the end of the packet if that is longer than 250µS. Then it goes to standby-I mode for the rest of the specified ARD. After the ARD it goes to TX mode and then retransmits the packet.

b. The RX_DR IRQ is asserted by a new packet arrival event. The procedure for handling this interrupt should be: 1) read payload through SPI, 2) clear RX_DR IRQ, 3) read FIFO_STATUS to check if there are more payloads available in RX FIFO, 4) if there are more data in RX FIFO, repeat from 1)

c. To activate this feature use the ACTIVATE SPI command followed by data 0x73. The corresponding bits in the FEATURE register must be set.

d. If ACK packet payload is activated, ACK packets have dynamic payload lengths and the Dynamic Payload Length feature should be enabled for pipe 0 on the PTX and PRX. This is to ensure that they receive the ACK packets with payloads. If the payload in ACK is more than 15 byte in 2Mbps mode the ARD must be 500µS or more, and if the payload is more than 5byte in 1Mbps mode the ARD must be 500µS or more.

Table 21. Register map of the RF Transceiver

7   USB Interface

The USB devices controller provides a full speed USB function interface that meets the 1.1 and 2.0 revision of the USB specification. It handles byte transfers autonomously and bridges the USB interface to a simple read/write parallel interface.

7.1   Features

- Serial Interface Engine
  - ► Supports full speed devices
  - ► Extraction of clock and data signals in internal DPLL
  - ► NRZI decoding/encoding
  - ► Bit stuffing/stripping
  - ► CRC checking/generation
  - ► On-chip transceiver
  - ► On-chip pull-up resistor on D+ with software controlled disconnect
- 2 control, 10 bulk/interrupt and 2 ISO endpoints
  - ► Supports control transfers by endpoint #0
  - ► Supports bulk, interrupt on endpoint #1 - #5 (in/out)
  - ► Support double buffering for isochronous endpoint #8 (in/out)
  - ► Programmable double buffering for bulk and interrupt endpoints
- Automatic data retry mechanism
- Data toggle synchronization mechanism
- Suspend and resume power management functions
- Remote Wakeup function
- Flexible endpoint buffers RAM
  - ► 512 bytes buffer total
  - ► Up to 64 bytes buffer size for endpoint 0-5
  - ► Up to 128bytes buffer size for endpoint 8

The endpoint set up allows for five different applications (for example, Mouse, Keyboard, Remote Control, Gamepad and Joystick) to use both input and output data transfer on separate endpoints.

The nRF24LU1 supports a total of 14 endpoints. EP0 IN/OUT supports input and output control data transfer, EP1-5 IN/OUT supports input and output bulk and interrupt data transfer. In addition, EP8 IN/OUT can be configured for input and output isochronous data transfer. These two endpoints share memory buffer area with EP0-5. This sharing is controlled by nRF24LU1 firmware.

7.2 Functional

The USB module is designed to serve as a Full Speed (FS) USB device as defined in the Universal Serial Bus Specification Rev 2.0. It is controlled both with SFR registers and XDATA mapped registers. There are two SFR registers, `USBCON` and `USBSLP`, and the rest of the registers are XDATA mapped registers.

Address	Reset value	Bit	Name	R/W	Description
0xA0	0xFF	7	swrst	RW	1: reset USB
		6	wu	RW	1: wakeup USB, must be cleared before setting USBSLP.
		5	suspend	R	1: USB is suspended. This bit acknowledges USBSLP=1, after a delay of up to 32µs.
		4-0	iv4.0	R	Interrupt vector, see Table 32. on page 81

Table 22. USBCON register

Address	Reset value	Bit	Name	R/W	Description
0xD9	0x00	7:1	-	-	Not used
		0	Sleep	WO	1: Disable USB clock, bit automatically cleared.

Set wu=1 in USBCON to enable USB clock

Table 23. USBSLP register

The other USB registers and buffer RAM are accessible through a 2k "window" in XDATA space using the MOVX instruction.

Note: Undefined addresses should not be written or read.

Table 24.USB buffer and register map

7.3   Control endpoints

Each USB device is allocated by endpoint numbers. The endpoint 0 (EP0) is reserved for control transfers. Using USB requests, the host uses EP0 for device configuration.

The device processes the SET_ADDRESS request and sets the address in the fnaddr register. Firmware interrupts this request as configured in the usbien register.

All other USB device requests must be processed by firmware.

7.3.1   Control endpoint 0 implementation

Every USB device must have the endpoint 0, it is the special control endpoint.

7.3.2 Endpoint 0 registers

Register name	Bit name	Bit description
usbien(0)	sudavie	Setup data valid interrupt enable
usbien(2)	sutokie	Setup token interrupt enable
usbirq(0)	sudavir	Setup data valid interrupt request
usbirq(2)	sutokir	Setup token interrupt request
setupdat0 setupdat7	Setup Data Buffer	8 bytes setup data packet
in_irq(0)	in0ir	IN 0 endpoint interrupt request
out_irq(0)	out0ir	OUT 0 endpoint interrupt request

out_ien(0)	out0ien	OUT 0 endpoint interrupt enable
ep0cs(0)	ep0stall	Endpoint 0 STALL bit
ep0cs(1)	hsnak	Handshake NAK
ep0cs(2)	inbsy	IN 0 buffer busy flag
ep0cs(3)	outbsy	OUT 0 buffer busy flag
ep0cs(4)	dstall	Send STALL in the data stage
ep0cs(5)	chgset	Setup Buffer content was changed
in0bc	Register	IN 0 byte counter
out0bc	Register	OUT 0 byte counter

Table 25. Endpoint 0 Register

7.3.3 Control transfer examples

A control transfer consists of two or three stages:

- Setup stage
- Data stage (optional)
- Status stage

7.3.3.1 Control write transfer example
Figure 26. Control Write Transfer

After receiving the SETUP token, the USB controller sets the hsnak and sutokir bits. If an 8-byte data packet is received correctly, the USB controller sets the sudavir bit. Setting sutokir and (or) sudavir bits generates the appropriate interrupts. The data stage consists of one or more OUT bulk-like transactions.

The USB controller generates the OUT 0 interrupt request by setting the out0ir bit after each correct OUT transaction during the data stage. Out0bc register contains the number of data bytes received in the last OUT transaction. The MCU services the interrupt request and then prepares the endpoint for the next transaction by reloading the out0bc register with any value (setting `outbsy` bit). The status stage of a control transfer is the last operation in the sequence.

The MCU clears the hsnak bit (by writing 1 to it) to instruct the USB controller to ACK the status stage. The USB controller sends a STALL handshake when both hsnak and stall bits are set.

7.3.3.2 Control read transfer example

Setup Stage:

| SETUP Token | 8 Bytes Data0 Packet | ACK Packet |

SETUP(0)

set sutokir, set hsnak → set sudavir

setupdat buffer now contains data that arrived in data0 packet

☐ Host to Device
☐ Device to Host

Data Stage:

| IN Token | Payload Data1 Packet | ACK Packet |

IN (1)

set in0ir

Microcontroller services in0 interrupt request and reloads in0bc register

| IN Token | Payload Data0 Packet | ACK Packet |

IN(0)

● ● ●

→ set in0ir

Status Stage:

| OUT Token | 0 Bytes Data1 Packet | NAK Packet |

OUT (1)

● ● ●

Microcontroller clears hsnak or dstall (or sets stall bit)

| OUT Token | 0 Bytes Data1 Packet | ACK Packet |

OUT(1)

Figure 27. Control Read Transfer

Control read transfer is similar to control write transfer with the only difference in the data stage. During the data stage of control read transfers, the USB controller generates the IN 0 interrupt request by setting in0ir bit. This is done after each acknowledge by the host data packet. The MCU loads new data into the IN 0 buffer and then reloads the in0bc register with a valid number of loaded data. Reloading the in0bc register causes the inbsy bit to set and arms the endpoint for the next IN transaction.

The status stage of a control transfer is the last operation in the sequence. The MCU clears the hsnak bit (by writing 1 to it) to instruct the USB controller to ACK the status stage. The USB controller sends the STALL handshake when both hsnak and stall bits are set.

7.3.3.3 No-data control transfer example

Setup Stage:

| SETUP Token | 8 Bytes Data0 Packet | ACK Packet |

SETUP(0)

set sutokir, set hsnak → set sudavir

setupdat buffer now contains data that arrived in data0 packet

☐ Host to Device
☐ Device to Host

Status Stage:

| IN Token | NAK Packet |

● ● ●

Microcontroller clears hsnak (or sets stall bit)

| IN Token | 0 Bytes Data1 Packet | ACK Packet |

IN(1)
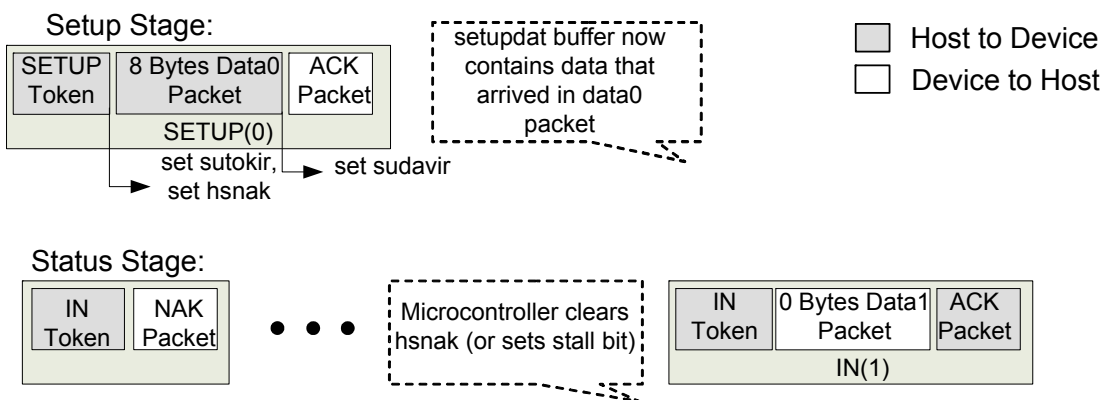

Figure 28. No-data Control Transfer

Some control transfers do not have a data stage. In this case the status stage consists of the IN data packet. The MCU clears the hsnak bit (by writing 1 to it) to instruct the USB controller to ACK (acknowledge) the status stage.

7.4 Bulk/Interrupt endpoints

Each USB transaction is formed as a token packet, optional data packet and, optional handshake packet.

Data transfers consist of two or three phases:

- Token packet
- Data packet
- Handshake packet (optional)

Only control, bulk and, interrupt transfers have their own handshake phase.

Isochronous transfers do not contain a handshake phase. Data is transferred during the data packet phase. Two PID types are available for this: DATA0 and DATA1.

7.4.1 Bulk/Interrupt endpoints implementation

The USB controller has 1 to 5 bulk IN endpoints and 1 to 5 bulk OUT endpoints.

7.4.2 Bulk/Interrupt endpoints registers

Register name	Bit name	Bit description
inbulkval(x)	Inxval	IN x endpoint valid (x = endpoint number)
usbpair	Register	Endpoint pairing register
in_ien(x)	Inxien	IN x endpoint interrupt enable (x = endpoint number)
inxbuf	Buffer	Endpoint x buffer (x = endpoint number)
inxbc	Register	IN x byte count register (x = endpoint number)
inxcs(0)	inxstl	IN x endpoint stall bit (x = endpoint number)
inxcs(1)	inxbsy	IN x endpoint busy bit (x = endpoint number)
in_irq(x)	inxir	IN x endpoint interrupt request

Table 26. Bulk/Interrupt IN endpoints registers

Register name	Bit name	Bit description
out-bulkval(x)	Outxval	OUT x endpoint valid (x = endpoint number)
usbpair	Register	Endpoint pairing register
out_ien(x)	Outxien	OUT x endpoint interrupt enable (x = endpoint number)
outxbuf	Buffer	Endpoint x buffer (x = endpoint number)
outxbc	Register	OUT x byte count register (x = endpoint number)
outxcs(0)	Outxstl	OUT x endpoint stall bit (x = endpoint number)
outxcs(1)	Outxbsy	OUT x endpoint busy bit (x = endpoint number)
out_irq(x)	Outxir	OUT x endpoint interrupt request

Table 27. Bulk OUT endpoints registers

7.4.3   Bulk and interrupt endpoints initialization

The MCU sets the appropriate valid bits in the in(out)bulkval register to enable bulk IN (OUT) endpoints for normal operation.

7.4.3.1   Bulk and interrupt transfers

a) IN transfers
Figure 29. Bulk IN transfer

The host issues an IN token to receive bulk data. If the inxbsy bit is set, the USB controller responds by returning a data packet. If the host receives a valid data packet, it responds with an ACK handshake.

After receiving a valid ACK handshake from the host, the USB controller sets the inxir bit and clears the inxbsy bit. Setting the inxir bit generates an interrupt request for IN x endpoint (x = appropriate number of endpoint).

The MCU services the interrupt request. During a service interrupt request the MCU loads new data into the inxbuf buffer and then reloads the inxbc register with a valid number of data bytes to set the inxbsy bit. IN x endpoint is armed for the next transfer when the inxbsy bit is set.

When the inxbsy bit is not set, the USB controller returns NAK handshake for each IN token from the host. When the inxstl bit is set, the USB controller returns the STALL handshake.

Errors in IN token	Inxbsy	Inxstl	USB controller to host response
NO	1	0	Inxbc bytes data packet
NO	0	1	STALL
NO	0	0	NAK
NO	1	1	STALL
YES	-	-	No response

Table 28. The USB controller response for IN Token

b) OUT transfers
Figure 30. Bulk OUT transfer

When the host wants to transmit bulk data, it issues an OUT Token packet followed by a data packet. An ACK handshake is returned to the host and the outxir bit is set when the USB controller receives an error free OUT, data packets and, the outxbsy bit is set. Setting the outxir bit generates an interrupt request for the OUT x endpoint (x = appropriate number of endpoints).

The MCU services the OUT x interrupt request. The received data packet is available in the outxbuf buffer. After servicing an interrupt request, the MCU reloads the outxbc register with any value to set the outxbsy bit. When the outxbsy bit is set the OUT x endpoint is armed for the next OUT transfer.

A NAK handshake is returned to the host when the USB controller receives data packets and an error free OUT but the outxbsy bit is not set.

A STALL handshake is returned to the host when the USB controller receives an error free OUT and data packets and the outxstl bit is set. The USB controller does not return a handshake if any transmission error occurs during an OUT token or data phase.

Errors in OUT token or in data packet	outxbsy	outxstl	USB controller to host response
NO	0	0	NAK
NO	0	1	STALL
NO	1	0	ACK
NO	1	1	STALL
YES	-	-	No response

Table 29. The USB controller response for OUT transfers

7.4.4   Data packet synchronization

Data packet synchronization is achieved through the use of the data sequence toggle bits and the DATA0/ DATA1 PIDs. The USB controller automatically toggles DATA0/DATA1 PIDs every bulk transfer.

The MCU can directly set or clear data toggle bits using the togctl register. The MCU clears the toggle bits when the host issues Clear Feature, Set Interface or, selects alternate settings.

To write a toggle bit the MCU performs the following sequence:

- Write to togctl register "000d0eee" value to select endpoint "eee" ("eee" – binary value). Endpoint direction bit "d": "d"='0' – OUT endpoint; "d"='1' – IN endpoint.
- Clear or set toggle bit by writing to togctl register "0srd0eee" value. "sr"='10' – setting toggle bit; "sr"='01' – clearing toggle bit.

7.4.5 Endpoint pairing

To enable double buffering the MCU sets the appropriate bits in the usbpair register to '1' (see section 15.1 on page 123).

When double buffering is enabled, the MCU may access one buffer of the pair while the USB host accesses the other. When an endpoint is paired, the MCU uses only an even numbered endpoint of the pair.

For example, if the usbpair(0) bit is set, that means that the IN 2 and the IN 3 endpoints are paired. The MCU should not access in3buf data buffer, in3val bit, in3bc register, in3ir bit, in3ien bit, or in3cs registers.

7.4.5.1 Paired IN endpoint status

When both endpoint buffers of the pair are filled and armed, the inxbsy bit is set to '1' by the USB controller and the MCU does not load new data into the inxbuf buffer.

When one or both buffers of the pair are empty (unarmed), the inxbsy bit is set to '0' by the USB controller and the MCU may fill inxbuf with new data and reload the inxbc register to arm the endpoint for transmission. Clearing the inxbsy bit (write a '1') causes both of the paired endpoints to unarm. An interrupt request is generated after each data packet is correctly sent, independent of the inxbsy bit.

7.4.5.2 Paired OUT endpoint status

When the MCU pairs OUT endpoints by setting bit in the usbpair register, it also reloads twice the outxbc register to arm paired OUT endpoints.

When both endpoint buffers of the pair are empty and no data is available for the MCU, the outxbsy bit is set to '1' by the USB controller.

When one or both of the buffers contain valid data, the outxbsy bit is reset to '0' by the USB controller. Clearing the outxbsy bit (write a '1') causes both of the paired endpoints to unarm. An interrupt request is generated after each data packet is correctly received, independent of outxbsy bit or dstall. To receive an interrupt you must arm the endpoint by setting outxbc to a non-zero value.

7.5 Isochronous endpoints

Isochronous (ISO) transactions have a token and a data phase, but no handshake phase. ISO transactions do not support a handshake phase or retry capability and they do not support a data toggle synchronization mechanism.

Isochronous transmission is double buffered. An ISO FIFO swap occurs for every start of frame packet.

7.5.1 Isochronous endpoints implementation

The USB controller contains one IN endpoint and one isochronous OUT endpoint (Endpoint 8 IN/OUT).

7.5.2 Isochronous endpoints registers

Register name	Bit name	Bit description
inisoval	in8val	IN 8 endpoint valid
in8addr	register	IN 8 endpoint address register
usbpair(7)	isosend0	ISO endpoints send a zero length data packet if it is empty
usbien(1)	sofie	Start of Frame interrupt enable
in8data	register	IN 8 endpoint data register
usbirq(1)	sofir	Start of Frame interrupt request

Table 30. ISO IN endpoint registers

Register name	Bit name	Bit description
outisoval	out8val	OUT 8 endpoint valid
out8addr	register	OUT 8 endpoint address register
usbien(1)	sofie	Start of Frame interrupt enable
out8data	register	OUT 8 endpoint data register
usbirq(1)	sofir	Start of Frame interrupt request
out8bch	register	Received byte count register high
out8bcl	register	Received byte count register low
isoerr	iso8err	OUT 8 endpoint CRC error

Table 31. ISO OUT endpoint registers

7.5.3 ISO endpoints initialization

The MCU performs the following steps to enable isochronous IN (OUT) endpoints for normal operation:

- Sets the appropriate valid bits into the in(out)isoval register.
- Sets the endpoint's FIFO size by loading the start address into the in(out)8addr register.
- Sets the isosend0 bit into the usbpair register - for IN endpoints only.
- Enables the start of frame interrupt by setting the sofie bit in the usbien register.

7.5.4 ISO transfers

The MCU serves all the ISO endpoints in response to a start of frame interrupt request.

7.5.4.1 ISO IN transfers
Figure 31. ISO IN transfer

The MCU loads new data into the ISO IN endpoint buffer(s) at every start of frame interrupt request. The ISO IN endpoint is accessed through the in8data register. The USB controller keeps track of the number of bytes that the MCU loads and sends loaded data during the next frame.

When the host wants to receive ISO data, it issues an IN token for a specific endpoint. If the IN buffer the host selected contains data, the USB controller responds by returning a data packet.

If the buffer is empty the USB controller behavior depends on the isosend0 bit:

- If the isosend0 bit is set, the USB controller responds with a zero byte length data packet.
- If the isosend0 bit is not set, USB controller does not respond.

7.5.4.2   ISO OUT transfers
Figure 32. ISO OUT transfer

With every start of frame interrupt request the MCU reads data that was sent by the host in the previous frame. Out8bch and out8bcl registers contain the number of transferred bytes. Data is accessible through the out8data register. The USB controller sets the iso8err bit when the ISO data packet is corrupted.

7.6   Memory configuration

7.6.1   On-chip memory map

All endpoint buffers are located in a single 512 byte memory block. Bulk OUT buffers block start at usbramaddr=000h. You can program localization of the Bulk IN buffers using binstaddr register. If the host sends a packet which is larger than the configured buffer size, the USB controller will not NAK or STALL.

You can program start of ISO buffers using isostaddr register. Additionally, program size of the ISO buffers using isosize register.

> **Note:** All ISO endpoints are double buffered.

Figure 33. shows on-chip memory organization. See Appendix B on page 170 for various USB memory configurations.
Figure 33. On-chip memory map

7.6.2 Setting ISO FIFO size

128 byte ISO buffers memory may be distributed over the two endpoint addresses: EP8 IN and EP8 OUT. The MCU initializes the endpoint FIFO sizes by setting the starting address for each FIFO. The first FIFO starting address is 0x000H. The size of an isochronous endpoint FIFO is determined by subtracting consecutive values of FIFO 8 starting addresses.

Note: Only the six most significant bits can be written by the MCU (see Figure 34. on page 76).
Figure 34. FIFO 8 starting address

The LSB values of the in(out)8addr register are always zero, that is, the smallest size of FIFO buffer for each ISO endpoints is 16 bytes.

7.6.3   Setting Bulk OUT size

8-bit boutxaddr register

| addr9 | addr8 | addr7 | addr6 | addr5 | addr4 | addr3 | addr2 | 0 |

Bulk OUT x starting address
Figure 35. Bulk OUT x starting address

Bulk OUT buffers memory can be distributed over the 6 bulk OUT endpoints. Size of each Bulk OUT endpoint should be programmed using boutxaddr registers. When OUT x endpoint is not used the boutxaddr for this endpoint should be set to 000h.

The first starting address (EP0 OUT) is 000H. The size of a bulk OUT endpoint is determined by subtracting consecutive values of bulk OUT x starting addresses. The size of Bulk OUT buffer is a multiple of two bytes.

Here is an example initialization of the boutxaddr registers:

```
constant EP0OUTSTARTADDR: INTEGER:=0;-- start address for EP0 OUT
bout1addr = EP0OUTSTARTADDR + (EP0OUT_SIZE/2);
bout2addr = bout1addr + (EP1OUT_SIZE/2);
bout3addr = bout2addr + (EP2OUT_SIZE/2);
bout4addr = bout3addr + (EP3OUT_SIZE/2);
bout5addr = bout4addr + (EP4OUT_SIZE/2);
binstaddr = (bout5addr + (EP5OUT_SIZE/2))/2;    -- beginning of
Bulk IN buffers
```

7.6.4   Setting Bulk IN size

8-bit binxaddr register

| addr9 | addr8 | addr7 | addr6 | addr5 | addr4 | addr3 | addr2 | 0 |

Bulk IN x starting address
Figure 36. Bulk IN x starting address

Bulk IN buffers memory can be distributed over the 6 bulk IN endpoints. Size of each bulk IN endpoint is programmed using binxaddr registers.

When IN x endpoint does not exist (or is not used) the binxaddr for it should be set to 000h. The first start-ing address (EP0 IN) is 000H. The size of a Bulk IN endpoint is determined by subtracting consecutive val-ues of Bulk IN x starting addresses. The size of Bulk IN buffer is a multiple of two bytes.

Here is an example initialization of the binxaddr registers:

```
constant EP0OUTSTARTADDR: INTEGER:=0;-- start address for EP0 IN
bin1addr = EP0OUTSTARTADDR + (EP0IN_SIZE/2);
bin2addr = bin1addr + (EP1IN_SIZE/2);
bin3addr = bin2addr + (EP2IN_SIZE/2);
bin4addr = bin3addr + (EP3IN_SIZE/2);
bin5addr = bin4addr + (EP4IN_SIZE/2);
isostaddr = (bin5addr + (EP5IN_SIZE/2))/8 + binstaddr/4;  --
beginning of the ISO
                                                buffers
```

7.7   The USB controller interrupts

The USB controller provides the two following interrupt signals for MCUs:

- USBWU
- USBIRQ

The USB controller generates interrupts by setting the USBWU or USBIRQ signal high and then setting it low. This interrupt request pulse is detected by the MCU as an edge triggered interrupt.

7.7.1   Wakeup interrupt request

When the USB controller is suspended by the host, it can be resumed in two ways:

- By the MCU setting the wakeup bit6 of USBCON SFR register.
- By receiving a resume request from the host.

After resuming, the USB controller generates a wakeup interrupt request by setting the USBWU signal high.

7.7.2   USB interrupt request

The USB interrupt request is provided through the USBIRQ signal and includes:

- 12 bulk endpoint interrupts
- Start of frame interrupt (sofir)
- Suspend interrupt (suspir)
- USB reset interrupt (uresir)
- Setup token interrupt (sutokir)
- Setup data valid interrupt (sudavir)

Figure 37. on page 80 shows all the interrupt sources and their natural priority.

After servicing the USB controller interrupt, the MCU clears the individual interrupt request flag in the USB registers. If any other USB interrupts are pending, the act of clearing the interrupt request flag causes the

USB controller to generate another pulse for the highest priority pending interrupt. If more than one interrupt is pending, each is serviced in the priority order.

The sequence of clearing the interrupt requests is important. The MCU first clears the main interrupt request flag (USBIRQ) and then each individual interrupt request in the USB controller register (usbirq).

Clearing the interrupt source immediately generates an interrupt pulse for the next pending interrupt. The interrupt may be lost when the MCU clears the main interrupt request flag after clearing the individual interrupt source.

Note: There is a difference between the interrupt USBIRQ, which is defined in Table 135., and the register usbirq described in Table 42.
Figure 37. The USB controller interrupt sources

7.7.3 USB interrupt vectors

The USB controller prioritizes the USB interrupts if two or more occur simultaneously. The vector of the active interrupt is available in the ivec register. Table 32. shows the contents of the ivec register for the USB interrupts.

Source of interrupt	Register bit	Contents of ivec register
sudav	usbirq(0)	0x00H
sof	usbirq(1)	0x04H
sutok	usbirq(2)	0x08H
suspend	usbirq(3)	0x0CH
usbreset	usbirq(4)	0x10H
ep0in	In_irq(0)	0x18H
ep0out	out07irq(0)	0x1CH
ep1in	In_irq(1)	0x20H
ep1out	out07irq(1)	0x24H
ep2in	In_irq(2)	0x28H
ep2out	out07irq(2)	0x2CH
ep3in	In_irq(3)	0x30H
ep3out	out07irq(3)	0x34H
ep4in	In_irq(4)	0x38H
ep4out	out07irq(4)	0x3CH
ep5in	In_irq(5)	0x40H
ep5out	out07irq(5)	0x44H

Table 32. Interrupt vectors

7.8 The USB controller registers

The microprocessor interfaces with the USB controller logic through the following registers and RAM buffers.

7.8.1 Bulk IN data buffers (inxbuf)

Six 32 byte bulk IN buffers are in RAM memory.

Address	Name	Function
0xC700H-0xC71FH	in0buf	32 bytes bulk 0 IN buffer
0xC680H-0xC69FH	in1buf	32 bytes bulk 1 IN buffer
0xC600H-0xC61FH	in2buf	32 bytes bulk 2 IN buffer
0xC580H-0xC59FH	in3buf	32 bytes bulk 3 IN buffer
0xC500H-0xC51FH	in4buf	32 bytes bulk 4 IN buffer
0xC480H-0xC49FH	in5buf	32 bytes bulk 5 IN buffer

Table 33. Bulk IN endpoints memory locations

7.8.2 Bulk OUT data buffers (outxbuf)

Six 32 byte bulk OUT buffers are in RAM memory.

Address	Name	Function
0xC6C0H-0xC6FFH	out0buf	32 bytes bulk 0 OUT buffer
0xC640H-0xC67FH	out1buf	32 bytes bulk 1 OUT buffer
0xC5C0H-0xC5FFH	out2buf	32 bytes bulk 2 OUT buffer
0xC540H-0xC57FH	out3buf	32 bytes bulk 3 OUT buffer
0xC4C0H-0xC4FFH	out4buf	32 bytes bulk 4 OUT buffer
0xC440H-0xC47FH	out5buf	32 bytes bulk 5 OUT buffer

Table 34. Bulk OUT endpoints memory locations

7.8.3 Isochronous OUT endpoint data FIFO (out8dat)

Address	Name	Function
0xC760H	out8data	ISO OUT endpoint 8 data FIFO register

Table 35. The out8dat register

7.8.4 Isochronous IN endpoint data FIFOs (in8dat)

Address	Name	Function
0xC768H	in8data	ISO IN endpoint 8 FIFO data register

Table 36. The in8dat register

7.8.5 Isochronous data bytes counter (out8bch/out8bcl)

Address	Name	Function
0xC770H	out8bch	ISO OUT endpoint 8 data counter high
0xC771H	out8bcl	ISO OUT endpoint 8 data counter low

Table 37. The outxbch/bcl register

7.8.6 Isochronous transfer error register (isoerr)

Address	MSB							LSB
0xC7A0H	-	-	-	-	-	-	-	iso8err

Table 38. The isoerr register

The isoerr register is updated at every Start Of Frame. The iso8err bits indicate that an error occurred during the receiving of ISO OUT 8 endpoint data packet.

Iso8err bit = 1 means that a CRC error occurred, but received data is available in the out8data register.

7.8.7 The zero byte count for ISO OUT endpoints (zbcout)

Address	MSB							LSB
0xC7A2H	-	-	-	-	-	-	-	ep8

Table 39. The zbcout register

The ep8 bit is set to '1' when zero-byte ISO OUT data packet is received for OUT 8 endpoint in the previous frame.

7.8.8 Endpoints 0 to 5 IN interrupt request register (in_irq)

Address	MSB							LSB
0xC7A9H	-	-	in5ir	in4ir	in3ir	in2ir	in1ir	in0ir

Table 40. The in_irq register

inxir is set to '1' when IN packet transmits and ACK receives from the host. Firmware sets inxir to '1' to clear interrupt.

7.8.9 Endpoints 0 to 5 OUT interrupt request register (out_irq)

Address	MSB							LSB
0xC7AAH	-	-	out5ir	out4ir	out3ir	out2ir	out1ir	out0ir

Table 41. The out_irq register

outxir is set to '1' when OUT packet is received error free. Firmware sets outxir to '1' to clear interrupt.

7.8.10 The USB interrupt request register (usbirq)

Address	Bit	Name	Function
0xC7AB	7:5		Must be zero
	4	uresir	USB reset interrupt request 1: a USB bus reset is detected
	3	suspir	USB suspend interrupt request 1: USB SUSPEND signaling detected
	2	sutokir	SETUP token interrupt request 1: SETUP token detected
	1	sofir	Start of frame interrupt request 1: SOF packet received
	0	sudavir	SETUP data valid interrupt request 1: error free SETUP data packet received

Table 42. The usbirq bit functions

Firmware clears an interrupt request by writing '1' to the corresponding request bit.

7.8.11 Endpoint 0 to 5 IN interrupt enables (In_ien)

Address	MSB							LSB
0xC7AC	-	-	in5ien	in4ien	in3ien	in2ien	in1ien	in0ien

Table 43. The In_ien register

Firmware sets inxien to '1' to enable interrupt.

7.8.12 Endpoint 0 to 5 OUT interrupt enables (out_ien)

Address	MSB							LSB
0xC7AD	-	-	out5ien	out4ien	out3ien	out2ien	out1ien	out0ien

Table 44. The In_ien register

Firmware sets outxien to '1' to enable interrupt.

7.8.13 USB interrupt enable (usbien)

Address	Bit	Name	Function
0xC7AE	7:5	–	Must be zero
	4	uresie	USB reset to enable interrupt
	3	suspie	USB suspend to enable interrupt
	2	sutokie	SETUP token to enable interrupt
	1	sofie	Start of frame to enable interrupt
	0	sudavie	SETUP data valid to enable interrupt

Table 45. The usbien register

7.8.14   Endpoint 0 control and status register (ep0cs)

Address	Bit	Name	Function
0xC7B4	7:6	-	Must be zero
	5	chgset	Setup Buffer content was changed. Chgset=1 - setup buffer was changed. Chgset=0 - setup buffer was not changed. The MCU clears the chgset bit by writing a '1' to it. The chgset bit is automatically set when USB controller receives setup data packet.
	4	dstall	Send STALL in the data stage. If dstall bit is set to '1', the USB controller sends a STALL handshake for any IN or OUT token in the data stage. When dstall is set and USB controller sends STALL in the data stage, the ep0stall is automatically set to '1' and USB controller sends STALL handshake also in the status stage. dstall is automatically cleared when a SETUP token arrives. The MCU sets this bit by writing '1' to it. The MCU should set dstall bit after last successful trans-action in the data stage. When there were not excessive transactions in the data stage and the next transaction is in the correct status stage the USB controller will answer based on hsnak and ep0stall settings.
	3	outbsy	OUT0 endpoint busy bit. Outbsy is a read only bit that is automatically cleared when a SETUP token arrives. The MCU sets this bit by writing a dummy value to the out0bc register. 1: USB controller controls the OUT 0 endpoint buffer. 0: the MCU controls of the OUT 0 endpoint buffer.
	2	inbsy	IN0 endpoint busy bit. inbsy is a read only bit that is automatically cleared when a SETUP token arrives. The MCU sets this bit by reloading the in0bc register. 1: USB controller controls the IN 0 endpoint buffer. 0: the MCU controls the IN 0 endpoint buffer.
	1	hsnak	If hsnak bit is set to '1', the USB controller responds with a NAK handshake for every packet in the status stage. hsnak bit is automatically set when a SETUP token arrives. The MCU clears the hsnak bit by writing a '1' to it.
	0	ep0stall	Endpoint 0 stall. 1: the USB controller sends a STALL handshake for any IN or OUT token. This is done in the data or handshake phases of the CONTROL transfer. Ep0stall is automati-cally cleared when a SETUP token arrives. The MCU sets this bit by writing '1' to it.

Table 46. ep0cs register

7.8.15 Endpoint 0 to 5 IN byte count registers (inxbc)

Address	Name	Function
0xC7B5	in0bc	IN 0 endpoint byte count register
0xC7B7	in1bc	IN 1 endpoint byte count register
0xC7B9	in2bc	IN 2 endpoint byte count register
0xC7BB	in3bc	IN 3 endpoint byte count register
0xC7BD	in4bc	IN 4 endpoint byte count register
0xC7BF	in5bc	IN 5 endpoint byte count register

Table 47. Endpoint 0 to 5 IN byte count register locations

After loading the IN x endpoint buffer, the MCU writes to the inxbc register with the number of loaded bytes. Writing to the inxbc register causes the arming of IN x endpoint by setting the inxbsy bit to '1'.

When the host sends IN token for IN x endpoint and inxbsy bit is set, the USB controller responds with an inxbc size data packet.

7.8.16 Endpoint 1 to 5 IN control and status registers (inxcs)

Address	Name	Function
0xC7B6	in1cs	IN 1 endpoint control and status register
0xC7B8	in2cs	IN 2 endpoint control and status register
0xC7BA	in3cs	IN 3 endpoint control and status register
0xC7BC	in4cs	IN 4 endpoint control and status register
0xC7BE	in5cs	IN 5 endpoint control and status register

Table 48. Endpoint 1 to 5 IN control and status register locations

Bit	Symbol	Function
7:2	-	Not used.
1	inxbsy	IN x endpoint busy bit. 1: the USB controller takes control of the IN x endpoint buffer. 0: the MCU takes control of the IN x endpoint buffer. When the host sends an IN token for IN x endpoint and the inxbsy bit is set, the USB controller responds with inxbc size data packet and clears the inxbsy bit. 0: the IN x endpoint is empty and ready for loading by the MCU. 1: the MCU does not access the IN x endpoint buffer. A '1' to '0' transition of the inxbsy bit generates an interrupt request for the IN x endpoint. The MCU sets the inxbsy bit by reloading the inxbc register.
0	inxstl	IN x endpoint stall bit. 1: the USB controller returns a STALL handshake for all requests to the endpoint x.

Table 49. The inxcs register description

7.8.17 Endpoint 0 to 5 OUT byte count registers (outxbc)

Address	Name	Function
0xC7C5H	out0bc	OUT 0 endpoint byte count register
0xC7C7H	out1bc	OUT 1 endpoint byte count register
0xC7C9H	out2bc	OUT 2 endpoint byte count register
0xC7CBH	out3bc	OUT 3 endpoint byte count register
0xC7CDH	out4bc	OUT 4 endpoint byte count register
0xC7CFH	out5bc	OUT 5 endpoint byte count register

Table 50. Endpoint 0 to 5 OUT byte count register locations

The outxbc register contains the number of bytes sent during the last OUT transfer from the host to an OUT x endpoint. The outxbc is a read only register that is updated by the USB controller.

7.8.18 Endpoint 1 to 5 OUT control and status registers (outxcs)

Address	Name	Function
0x7C6H	Out1cs	OUT 1 endpoint control and status register
0x7C8H	Out2cs	OUT 2 endpoint control and status register
0x7CAH	Out3cs	OUT 3 endpoint control and status register
0x7CCH	Out4cs	OUT 4 endpoint control and status register
0x7CEH	Out5cs	OUT 5 endpoint control and status register

Table 51. Endpoint 1 to 5 OUT control and status register locations

Bit	Symbol	Function
	-	Not used
1	outxbsy	OUT x endpoint busy bit. 1: the USB controller takes control of the OUT x endpoint buffer. 0: the MCU takes control of the OUT x endpoint buffer. When the host sends an OUT token for an OUT x endpoint and the outxbsy bit is set, the USB controller receives an OUT data packet and clears the outxbsy bit. If outxbsy='1', the OUT x endpoint is empty and ready to receive the next data packet from the host. When outxbsy='1', the MCU does not read the OUT x endpoint buffer. A '1' to '0' transition of the outxbsy bit generates an interrupt request for the OUT x endpoint. The MCU sets the outxbsy bit by reloading the outxbc register with a dummy value.
0	outxstl	OUT x endpoint stall bit. If outxstl='1', the USB controller returns a STALL handshake for all requests to the endpoint x.

Table 52. The outxcs register description

7.8.19 USB control and status register (usbcs)

Address	Bit	Name	Function
0xC7D6	7	wakesrc	Wakeup source. This bit indicates that a wakeup pin resumed the USB controller. The MCU resets this bit by writing a '1' to it.
	6	-	Not used.
	5	sofgen	Sofgen= 1 - internal SOF timer is used to generate SOF interrupt in case when SOF issued by USB host was missed. Sofgen= 0 - internal SOF timer is disabled. Default value (after reset) is '0'.
	4	-	Not used.
	3	discon	1: Disconnect the 1.5 kohm internal pull-up resistor on D+ line, 0: Normal
	2	-	Not used.
	1	forcej	Forcej should be used only in the suspend state. The MCU should set forcej bit to drive J state on the USB lines and then clear forcej and set sigrsume to drive resume-K state on the USB lines. Forcing J state between idle and K state can be done to raise the crossover voltage and eliminate any false SE0.
	0	sigrsume	Signal remote device resume. If the MCU sets this bit to '1', the USB controller sets K state on the USB.

Table 53. The usbcs bit functions

7.8.20 Data toggle control register (togctl)

Address	Bit	Name	Function
0xC7D7	7	q	Data toggle value q='1' means that data toggle for endpoint selected by ep2,ep1,ep0 and io bits is set to DATA1. q='0' means that data toggle for endpoint selected by ep2,ep1,ep0 and io bits is set to DATA0. Before reading this bit, the MCU writes the ep2, ep1, ep0 and io bits.
	6	s	Set data toggle to DATA1. Writing '1' to this bit when endpoint is selected (ep2, ep1, ep0, io bits) causes setting the data toggle to DATA1.
	5	r	Reset data toggle to DATA0. Write '1' to this bit when endpoint is selected (ep2, ep1, ep0, io bits) causes setting data toggle to DATA0.
	4	io	Select IN or OUT endpoint io='1' selects IN endpoint, i0='0' selects OUT endpoint.
	3	-	Not used.
	2	ep2	Select number of endpoint. Valid values are 0 to 5 (000 – 101).
	1	ep1	
	0	ep0	

Table 54. The togctl bit functions

7.8.21 USB frame count low (usbframel/usbframeh)

Address	Name	Function
0xC7D8	usbframel	USB frame count low
0xC7D9	usbframeh	USB frame count high

Table 55. USB frame count low (usbframel/usbframeh)

The USB controller copies the frame count into the `usbframel` and `usbframeh` registers at every SOF (Start Of Frame). These registers are read only.

Note: Frame count wraps from 3ffh to 000h.

7.8.22 Function address register (fnaddr)

Address	Name	Function
0xC7DB	fnaddr	USB function address (1-127)

Table 56. Function address register (fnaddr)

The USB controller copies the "function address" which was sent by the host into the fnaddr register. The USB controller responds only with its assigned address. The fnaddr is a read only register.

7.8.23 USB endpoint pairing register (usbpair)

Address	Bit	Name	Function
0xC7DD	7	isosend0	ISO endpoints send zero length data packet. If the USB controller receives IN token for the isochronous endpoint and IN endpoint FIFO is empty, the USB controller response depends on the isosend0 bit. If isosend0='1', the USB controller sends a zero length data packet. If isosend0='0', the USB controller does not respond.
	6:5		Not used.
	4	pr4out	1: Pair bulk OUT 4 and bulk OUT 5 endpoints.
	3	pr2out	1: Pair bulk OUT 2 and bulk OUT 3 endpoints.
	2	pr6in	1: Pair bulk IN 6 and bulk IN 7 endpoints.
	1	pr4in	1: Pair bulk IN 4 and bulk IN 5 endpoints.
	0	pr2in	1: Pair bulk IN 2 and bulk IN 3 endpoints.

Table 57. The usbpair bit functions

7.8.24 Endpoints 0 to 5 IN valid bits (Inbulkval)

Address	MSB							LSB
0xC7DE	0	0	in5val	in4val	in3val	in2val	in1val	in0val

Table 58. The inbulkval register

If inxval='1', the IN x endpoint is active. When inxval='0', the IN x endpoint is inactive and the USB controller does not respond if IN x endpoint is addressed.

7.8.25 Endpoints 0 to 5 OUT valid bits (outbulkval)

Address	MSB							LSB
0xC7DF	0	0	out5val	out4val	out3val	out2val	out1val	out0val

Table 59. The outbulkval register

If outxval='1', the OUT x endpoint is active. When outxval='0', the OUT x endpoint is inactive and the USB controller does not respond if OUT x endpoint is addressed.

7.8.26 Isochronous IN endpoint valid bits (inisoval)

Address	MSB							LSB
0xC7E0	0	0	0	0	0	0	0	in8val

Table 60. The inisoval register

If in8val='1', the IN 8 endpoint is active. When in8val='0', the IN 8 endpoint is inactive and the USB controller does not respond if IN 8 endpoint is addressed.

7.8.27 Isochronous OUT endpoint valid bits (outisoval)

Address	MSB							LSB
0xC7E1	0	0	0	0	0	0	0	out8val

Table 61. The outisoval register

If out8val='1', the OUT 8 endpoint is active. When out8val='0', the OUT 8 endpoint is inactive and the USB controller does not respond if OUT 8 endpoint is addressed.

7.8.28 SETUP data buffer (setupbuf)

Address	MSB							LSB
0xCE8H-0xCEFH	D7	D6	D5	D4	D3	D2	D1	D0

Table 62. The setupbuf buffer

The setupbuf contains the 8 bytes of the SETUP data packet from the latest CONTROL transfer.

7.8.29 ISO OUT endpoint start address (out8addr)

Address	MSB							LSB
0xC7F0H	A9	A8	A7	A6	A5	A4	0	0

Table 63. The out8addr start address

7.8.30 ISO IN endpoint start address (in8addr)

Address	MSB							LSB
0xC7F8H	A9	A8	A7	A6	A5	A4	0	0

Table 64. The in8addr start address

8   Encryption/Decryption Unit

The nRF24LU1 has dedicated HW for data encryption or decryption according to the AES (Advanced Encryption Standard) algorithm. An AES encryption/decryption consists of the transformation of a 128-bit block into an encrypted 128-bit block.

8.1   Features

The AES block supports both encryption and decryption in ECB, CBC, CFB, OFB and CTR modes using a 128-bit key and optionally a 128-bit initialization vector.

8.1.1   ECB – Electronic Code Book

ECB is the most basic AES encryption/decryption mode. In encryption E the plaintext on DI is converted to a ciphertext on DO. In decryption D the ciphertext on DI is converted to plaintext on DO. ECB must use the last expanded key to decrypt. Decryption reverses encryption operations and is identical to the encryption function.
Figure 38. ECB – Electronic Code Book

8.1.2   CBC – Cipher Block Chaining

CBC adds a feedback mechanism to a block cipher. The result of the previous encryption operation is XOR'ed with incoming data. An initialization vector IV is used for the first iteration. CBC must use the last expanded key to decrypt. Decryption reverses encryption operations and is identical to the encryption function.
Figure 39. CBC – Cipher Block Chaining mode

8.1.3 CFB – Cipher FeedBack

In CFB the output of an encryption operation is fed back to the input of the AES block. An initialization vector IV is used for the first iteration. Input data is encrypted by XORing it with the output of the encryption module. Decryption reverses encryption operations and is identical to the encryption function.
Figure 40. CFB – Cipher FeedBack mode

8.1.4 OFB – Output FeedBack mode

In OFB the output of an encryption operation is fed back to the input of the AES core. An initialization vector IV is used for the first iteration. Input data is encrypted by XORing it with the output of the encryption module. Decryption reverses encryption operations and is identical to the encryption function.
Figure 41. OFB – Output FeedBack mode

8.1.5 CTR – Counter mode

In CTR the output of a counter is the input of the AES core. An initialization vector IV is used to initialize the counter. Input data is encrypted by XORing it with the output of the encryption module. Decryption reverses encryption operations and is identical to the encryption function.
Figure 42. CTR – Counter mode

8.2 Functional description

The MCU initializes the AES block with key (`AESKIN`) and optionally the initialization vector (`AESIV`). Then the MCU loads a 128-bit block into AESD, selects mode and starts the operation with `AESCS`.

When the result is ready, the AESIRQ is asserted and the MCU reads out the `AESD` register. Alternatively, the AESCS.0 can be polled instead of using interrupts.

Address	Reset value	Bit	Name	Description
0xE8	0x00	7:5	-	Not used
		4:2	mode	Type of AES encryption/decryption 000: CBC, 001: CFB, 010: OFB, 011: CTR, 100: ECB
		1	decr	0: Encrypt, 1: Decrypt
		0	go	Set by SW to '1' to start operation. SW can poll this signal to check if AES block is busy. Automatically reset by HW when operation is completed. An encrypt or decrypt operation takes about 45 Cclk cycles.

Table 65. AESCS register

The `AESKIN`, `AESIV` and `AESD` are 128-bit registers. In order to update or read one of these registers, 16 consecutive write (or read) operations to a single register are required.

The order of writing (or reading) to update a register in nRF24LU1 begins with the last (16th) operation and works back to the first.

AES data sets are normally organized in two dimensional arrays (ai,j):

a0,0	a0,1	a0,2	a0,3
a1,0	a1,1	a1,2	a1,3
a2,0	a2,1	a2,2	a2,3
a3,0	a3,1	a3,2	a3,3

Table 66. A two dimensional array

The array position to write to is decided by AESIA1 which contains two 4 bit pointers for the AESKIN regis-ter and the AESIV register. These pointers are incremented by each read/write to AESKIN or AESIV. After 16 reads/writes, the pointers wrap around to the starting value.

The relation of the byte pointer address n and the position in the AES array (ai,j) is given by the following definition:

$i = n \bmod 4$; $\quad j = [n / 4]$; $\quad n = 15 - i - 4 * j$

The relationship between the byte pointer address and the AES array position in nRF24LU1 is shown in Table 67. below:

n = 15	n = 11	n = 7	n = 3
n = 14	n = 10	n = 6	n = 2
n = 13	n = 9	n = 5	n = 1
n = 12	n = 8	n = 4	n = 0

Table 67. Relation between the byte pointer address and AES data array

Address	Reset value	Bit	R/W	Description
0xF1	0x00	7:0	RW	AESKIN
0xF2	0x00	7:0	RW	AESIV
0xF3	0x00	7:0	RW	AESD

Table 68. AESKIN, AESIV and AESD registers

A partial update can be done by using the AESIA1 or AESIA2 registers (see Table 69. and Table 70.).

By setting AESIA1 a single byte or a smaller block can be updated.

Address	Reset value	Bit	Name	Description
0xF5	0x00	7:4	ia_kin	AESKIN byte pointer address
		3:0	ia_iv	AESIV byte pointer address

Table 69. AESIA1 register

The `AESIA2` works like `AESIA1`, but only contains a 4-bit pointer for AESD.

Address	Reset value	Bit	Name	Description
0xF6	0x00	7:4	-	not used
		3:0	ia_data	AESD byte pointer address

Table 70. AESIA2 register

9 SPI master

The system features a simple single buffered SPI (Serial Programmable Interface) master working in mode 0, that is, capture MISO in rising SCK, and changing MOSI on falling SCK.

The SPI bus (MMISO, MSCK and MMOSI) are available at the programmable digital I/O. The SPI hardware does not generate any chip select signal. Another programmable digital I/O must be used to act as chip selects for one or more external SPI devices, see for details.

9.1 Features
Figure 43. Master SPI

9.2 Functional description

The SPI hardware is controlled by SFR registers SMDAT and SMCTRL.

Address	Reset value	Bit	R/W	Function
0xB2	0x00		R/W	SPI data input/output

Table 71. SMDAT register

Address	Reset value	Bit	R/W	Function
0xB3	0x00	7:5	-	Not used
		4	RW	00: disable, 01: enable
		3:0	RW	Divider factor from MCU clock (Cclk) to SPI clock frequency 0000: 1/2 of Cclk frequency 0001: 1/2 of Cclk frequency 0010: 1/4 of Cclk frequency 0011: 1/8 of Cclk frequency 0100: 1/16 of Cclk frequency 0101: 1/32 of Cclk frequency 0110: 1/64 of Cclk frequency other: 1/64 of Cclk frequency

Table 72. SMCTRL register.

9.3 SPI operation

A sequence of 8 pulses is started on MSCK every time you write to the SMDAT register. Also, the 8 bits of SMDAT register are clocked out on MMOSI with MSB clocking out first. Simultaneously, 8 bits from MMISO are clocked into SMDAT register. Output data is shifted on the negative edge of MSCK, and input data is read on the positive edge of MSCK. This is illustrated in Figure 44..

When the 8 bits from MMISO are finished, SPI_READY interrupt goes active, and the 8 bits from MMISO can be read from SMDAT register. The interrupt bit must be cleared, by writing to SMDAT register again, before starting another SPI transaction.
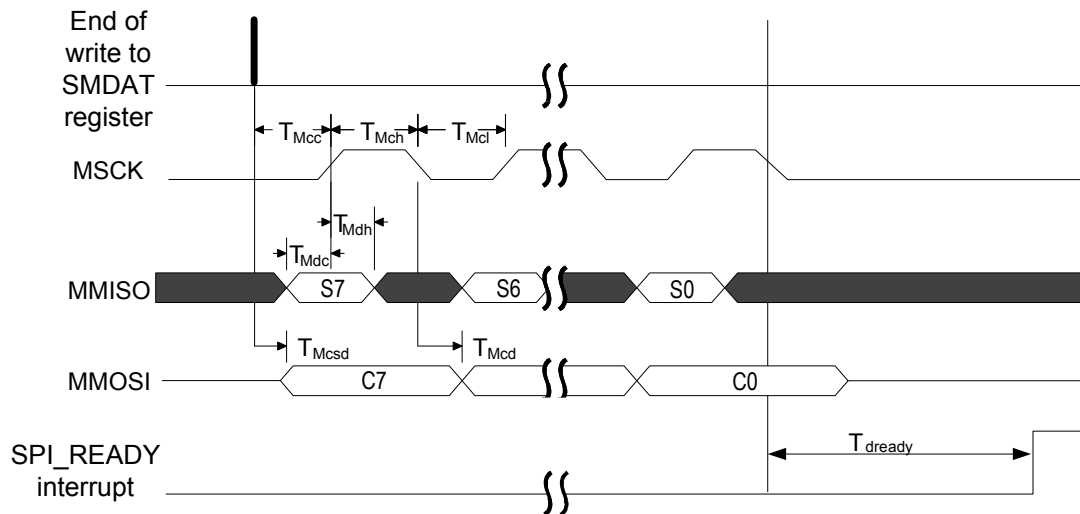

Figure 44. Master SPI timing

Value	Description
TMsck = TMch + TMcl	SCK cycle time, as defined by SMCTRL register.
TMcc	Time from writing to SMDAT register to first MSCK pulse, TMsck / 2.
TMcd	Delay from negative edge of MSCK to new MMOSI output data, may vary from -10ns to 10ns.
TMdc	MMISO setup time to positive edge of MSCK, TMdc > 45ns.
TMdh	MMISO hold time to positive edge of MSCK, TMdh > 0ns.
tdready	Time from last MSCK pulse to SPI_READY interrupt goes active. 7 MCU clock cycles.

Conditions: Output load= 10pF, MMISO rise/fall time=5ns.

Table 73. Master SPI timing values

Minimum time between two consecutive SPI transactions is: 8.5 Tsck + tdready + tSW where tSW is the time taken by the software to process SPI_READY interrupt and write to SMDAT register.

10   SPI slave

The system features a simple single buffered SPI (Serial Programmable Interface) slave working in mode 0, that is, capturing SMOSI on rising SSCK, and changing SMISO in falling SSCK.

The slave SPI monitors the `SCSN`, `SMOSI` and `SSCK` pins, and controls the `SMISO` pin. They are available on `P0.3` to `P0.0`, see chapter 13 on page 111 for details.The SPI slave may also be used for flash programming, see section 17.5.

10.1   Features
Figure 45. Slave SPI

10.2   Functional description

The following registers control the slave SPI.

Address	Reset value	Bit	R/W	Function
0xBC	0x00	7:6	-	Not used
		5	RW	1: Disable interrupt when SCSN goes high
		4	RW	1: Disable interrupt when SCSN goes low
		3	RW	1: Disable slave SPI interrupts
		2:1	-	Not used
		0	RW	1: Enable slave SPI

Table 74. SSCONF register

Address	Reset value	Bit	R/W	Function
0xBE	0x00	7:3	-	Not used
		2	R	1: Interrupt caused by positive edge of SCSN
		1	R	1: Interrupt caused by negative edge of SCSN
		0	R	1: Interrupt caused by data-byte sent or received[a]

a. If SPI is polled (no interrupts), then `IRCON.2` (see chapter 21.2.4 on page 161) should be polled, since reading SSSTAT clears the status-flags.

Table 75. SSSTAT register

Address	Reset value	Bit	R/W	Function
0xBD	0x00		RW	Data register

Table 76. SSDAT register

10.3   SPI timing
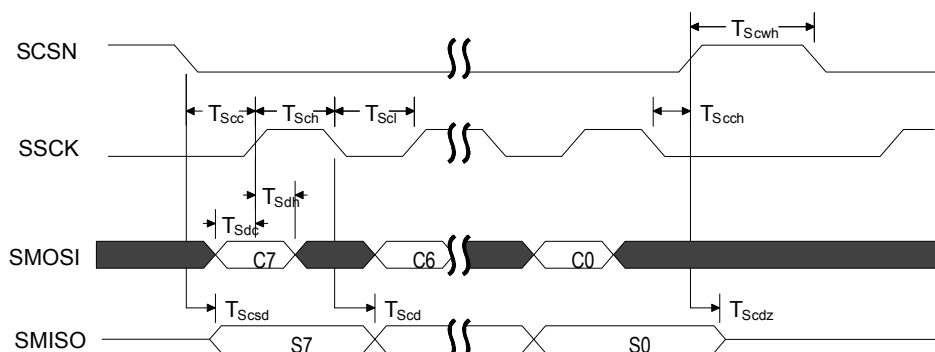

Figure 46. SPI NOP timing diagram)

Parameter	Symbol	Min.	Max	Units
SMOSI to SSCK Setup	TSdc	5		ns
SSCK to SMOSI Hold	TSdh	2		ns
SCSN to SMISO Valid	TScsd		TBD	ns
SSCK to SMISO Valid	TScd		42	ns
SSCK Low Time	TScl	50		ns
SSCK High Time	TSch	50		ns
SSCK Frequency	FSsck	0	8	MHz
SCSN to SSCK Setup	TScc	8		ns
SSCK to SCSN Hold	TScch	2		ns

SCSN to SMISO High Z	TScdz		TBD	ns

Conditions: SMISO load= 10pF, SSCK rise/fall time=2ns, other inputs rise/fall time=5ns.

Table 77. SPI timing parameters

11 Timer/Counters

The system includes three 16-bit timers/counters (Timer 0, Timer 1 and Timer 2). They can operate as either a timer with a clock rate based on the MCU clock, or as an event counter clocked by signals from the programmable digital I/O.

11.1 Features

11.1.1 Timer 0 and Timer 1

In timer mode, Timer 0/1 is incremented every 12 clock cycles.

In the counter mode, the Timer 0/1 is incremented when the falling edge is detected at the corresponding input pin T0 for Timer 0, or T1 for Timer 1.

Note: Timer input pins T0, T1 and, T2 must be configured as described in section 13.2 on page 112.

Since it takes two clock cycles to recognize a 1-to-0 event, the maximum input count rate is ½ of the oscillator frequency. There are no restrictions on the duty cycle, however to ensure proper recognition of 0 or 1 state, an input should be stable for at least 1 clock cycle.

Timer 0 and Timer 1 status and control are in TCON and TMOD register. The actual 16-bit Timer 0 value is in TH0 (8 msb) and TL0 (8 lsb), while Timer 1 use TH1 and TL1.

Four operating modes can be selected for Timer 0/1. Two Special Function Registers, TMOD and TCON, are used to select the appropriate mode.

11.1.1.1 Mode 0 and Mode 1

In mode 0, Timer 0/1 is configured as a 13-bit register (TL0/TL1 = 5 bits, TH0/TH1 = 8 bits). The upper three bits of TL0/TL1 are unchanged and should be ignored.

In mode 1 Timer 0/1 is configured as a 16-bit register.
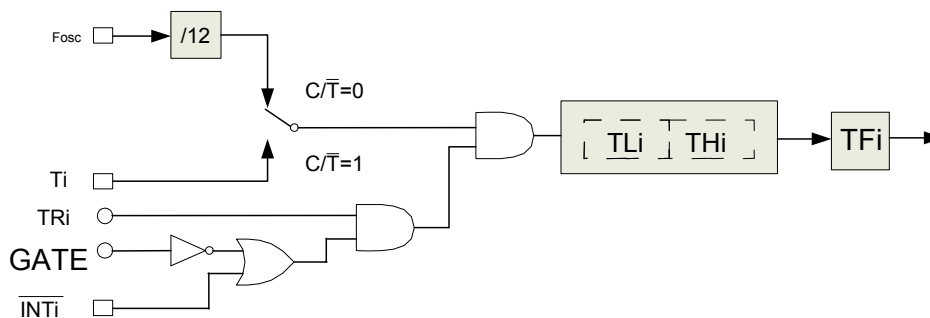

Figure 47. Timer 0 and Timer 1 in mode 0 and 1

11.1.1.2   Mode 2

In this mode, the Timer 0/1 is configured as an 8-bit register with auto reload.
Figure 48. Timer 0 and Timer 1 in mode 2

11.1.1.3   Mode 3

In mode 3 Timer 0/1 is configured as one 8-bit timer/counter and one 8-bit timer, but timer 1 in this mode holds its count. When Timer 0 works in mode 3 Timer 1 can still be used in other modes by the serial port as a baud rate generator, or as an application not requiring an interrupt from Timer 1.
Figure 49. Timer 0 in mode 3

11.1.2 Timer 2

Timer 2 is controlled by T2CON while the value is in TH2 and TL2. Timer 2 also has four capture and one compare/reload registers which can read a value without pausing or reload a new 16-bit value when Timer 2 reaches zero, see chapter 11.2.7 on page 106 and chapter 11.2.8 on page 106.
Figure 50. Timer 2 block diagram

11.1.2.1 Timer 2 description

Timer 2 can operate as a timer, event counter, or gated timer.
Figure 51. Timer 2 in Reload Mode

11.1.2.2 Timer mode

Timer mode is invoked by setting the t2i0=1 and t2i1=0 in the T2CON register. In this mode, the count rate is derived from the clk input.

Timer 2 is incremented every 12 or 24 clock cycles depending on the 2:1 prescaler. The prescaler mode is selected by bit t2ps of T2CON register. When t2ps=0, the timer counts up every 12 clock cycles, otherwise every 24 cycles.

11.1.2.3   Event counter mode

This mode is invoked by setting the t2i0=0 and t2i1=1 in the T2CON register.

In this mode, Timer 2 is incremented when external signal T2 (P0.5) (see section 13.2 on page 112 for more information on T2) changes its value from 1 to 0. The T2 input is sampled at every rising edge of the clock. Timer 2 is incremented in the cycle following the one in which the transition was detected. The maximum count rate is ½ of the clock frequency.

11.1.2.4   Gated timer mode

This mode is invoked by setting the t2i0=1 and t2i1=1 in the T2CON register.

In this mode, Timer 2 is incremented every 12 or 24 clock cycles (depending on T2CON t2ps flag). Additionally, it is gated by the external signal T2 (P0.5). When T2=0, Timer 2 is stopped.

11.1.2.5   Timer 2 reload

A 16-bit reload from the CRC register can be done in two modes:

- Reload Mode 0: Reload signal is generated by Timer 2 overflow (auto reload).
- Reload Mode 1: Reload signal is generated by negative transition at t2ex.

    Note: t2ex is connected to an internal clock signal which is half frequency of CKLF (see section 19.1.1 on page 150.

11.2   Functional description

11.2.1   Timer/Counter control register – TCON

TCON register reflects the current status of MCU Timer 0 and Timer 1 and it is used to control the operation of these modules.

Address	Reset value	Bit	Name	Auto clear	Description
0x88	0x00	7	tf1	Yes	Timer 1 overflow flag. Set by hardware when Timer1 overflows.
		6	tr1	No	Timer 1 Run control. If cleared, Timer 1 stops.
		5	tf0	Yes	Timer 0 overflow flag. Set by hardware when Timer 0 overflows.
		4	tr0	No	Timer 0 Run control. If cleared, Timer 0 stops.
		3	ie1	Yes	External interrupt 1 flag. Set by hardware.
		2	it1	No	External interrupt 1 type control. 1: falling edge, 0: low level
		1	ie0	Yes	External interrupt 0 flag. Set by hardware.
		0	it0	No	External interrupt 0 type control. 1: falling edge, 0: low level

Table 78. TCON register

The tf0, tf1 (timer 0 and timer 1 overflow flags), ie0 and ie1 (external interrupt 0 and 1 flags) are automatically cleared by hardware when the corresponding service routine is called.

11.2.2   Timer mode register - TMOD

TMOD register is used for configuration of Timer 0 and Timer1.

Address	Reset value	Bit	Name	Description
0x89	0x00	7	gate1	Timer 1 gate control
		6	ct1	Timer 1 counter/timer select. 1: Counter, 0: Timer
		5-4	mode1	Timer 1 mode 00 – Mode 0: 13-bit counter/timer 01 – Mode 1: 16-bit counter/timer 10 – Mode 2: 8-bit auto-reload timer 11 – Mode 3: Timer 1 stopped
		3	gate0	Timer 0 gate control
		2	ct0	Timer 0 counter/timer select. 1: Counter, 0: Timer
		1-0	mode0	Timer 0 mode 00 – Mode 0: 13-bit counter/timer 01 – Mode 1: 16-bit counter/timer 10 – Mode 2: 8-bit auto-reload timer 11 – Mode 3: two 8-bit timers/counters

Table 79. TMOD register

11.2.3   Timer0 – TH0, TL0

Address	Register name
0x8A	TL0
0x8C	TH0

Table 80. Timer 0 register (TH0:TL0)

These registers reflect the state of Timer 0. TH0 holds higher byte and TL0 holds lower byte. Timer 0 can be configured to operate as either a timer or a counter.

11.2.4   Timer1 – TH1, TL1

Address	Register name
0x8B	TL1
0x8D	TH1

Table 81. Timer 1 register (TH1:TL1)

These registers reflect the state of Timer 1. TH1 holds higher byte and TL1 holds lower byte. Timer 1 can be configured to operate as either timer or counter.

11.2.5 Timer 2 control register – T2CON

T2CON register reflects the current status of Timer 2 and is used to control the Timer 2 operation.

Address	Reset value	Bit	Name	Description
0xC8	0x00	7	t2ps	Prescaler select. 0: timer 2 is clocked with 1/12 of the Cclk frequency. 1: timer 2 is clocked with 1/24 of the Cclk frequency.
		6	i3fr	Int3 edge select. 0: falling edge, 1: rising edge
		5	i2fr	Int2 edge select: 0: falling edge, 1: rising edge
		4:3	t2r	Timer 2 reload mode. 0X – reload disabled, 10 – Mode 0, 11 – Mode 1
		2	t2cm	Timer 2 compare mode. 0: Mode 0, 1: Mode 1
		1-0	t2i	Timer 2 input select. 00: stopped, 01: f/12 or f/24, 10: falling edge of t2, 11: f/12 or f/24 gated by t2.

Table 82. T2CON register

11.2.6 Timer 2 – TH2, TL2

Address	Register name
0xCC	TL2
0xCD	TH2

Table 83. Timer 2 (TH2:TL2)

The TL2 and TH2 registers reflect the state of Timer 2. TH2 holds higher byte and TL2 holds lower byte. Timer 2 can be configured to operate in compare, capture or, reload modes.

11.2.7 Compare/Capture enable register – CCEN

The CCEN register serves as a configuration register for the Compare/Capture Unit associated with the Timer 2.

Address	Reset value	Bit	Name	Description
0xC1	0x00	7:6	coca3	compare/capture mode for CC3 register 00: compare/capture disabled 01: reserved 10: reserved 11: capture on write operation into register CCL3
		5:4	coca2	compare/capture mode for CC2 register 00: compare/capture disabled 01: reserved 10: reserved 11: capture on write operation into register CCL2
		3:2	coca1	compare/capture mode for CC1 register 00: compare/capture disabled 01: reserved 10: reserved 11: capture on write operation into register CCL1
		1:0	coca0	compare/capture mode for CRC register 00: compare/capture disabled 01: reserved 10: compare enabled 11: capture on write operation into register CRCL

Table 84. CCEN register

11.2.8 Capture registers – CC1, CC2, CC3

The Compare/Capture registers (CC1, CC2, CC3) are 16-bit registers used by the Compare/Capture Unit associated with the Timer 2. CCHn holds higher byte and CCLn holds lower byte of the CCn register.

Address	Register name
0xC2	CCL1
0xC3	CCH1
0xC4	CCL2
0xC5	CCH2
0xC6	CCL3
0xC7	CCH3

Table 85. Capture Registers - CC1, CC2 and CC3

11.2.9   Compare/Reload/Capture register – CRCH, CRCL

Address	Reset value	Register name
0xCA	0x00	CRCL
0xCB	0x00	CRCH

Table 86. Compare/Reload/Capture register - CRCH, CRCL

CRC (Compare/Reload/Capture) register is a 16-bit wide register used by the Compare/Capture Unit associated with Timer 2. CRCH holds higher byte and CRCL holds lower byte.

12   Serial Port (UART)

The MCU system is configured with one serial port that is identical in operation to the standard 8051 serial port (Serial interface 0). The two serial port signals RXD and TXD are available at the programmable digital I/O.

The serial port (UART) derives its clock from the MCU clock; Cclk. See for more information.

12.1   Features

The serial port is controlled by S0CON, while the actual data transferred is read or written in the S0BUF register. Transmission speed ("baud rate") is selected using the S0RELL, S0RELH and, WDCON registers.

12.2   Functional description

12.2.1   Serial Port 0 control register – S0CON

The S0CON register controls the function of Serial Port 0.

Address	Reset value	Bit	Name	Description
0x98	0x00	7:6	sm0: sm1	Serial Port 0 mode select 0 0: Mode 0 – Shift register at baud rate Cclk / 12 0 1: Mode 1 – 8-bit UART. Baud rate see table 1 0: Mode 2 – 9-bit UART at baud rate Cclk /32 or Cclk/64[a] 1 1: Mode 3 – 9 bit UART. Baud rate see below
		5	sm20	Multiprocessor communication enable
		4	ren0	Serial reception enable: 1: Enable Serial Port 0.
		3	tb80	Transmitter bit 8. This bit is used while transmitting data through Serial Port 0 in Modes 2 and 3. The state of this bit corresponds with the state of the 9th transmitted bit (for example, parity check or multi-processor communication). It is controlled by software.
		2	rb80	Received bit 8. This bit is used while receiving data through Serial Port 0 in Modes 2 and 3. It reflects the state of the 9th received bit.
		1	ti0	Transmit interrupt flag. It indicates completion of a serial transmission at Serial Port 0. It is set by hardware at the end of bit 8 in mode 0 or at the beginning of a stop bit in other modes. It must be cleared by software.
		0	ri0	Receive interrupt flag. It is set by hardware after completion of a serial reception at Serial Port 0. It is set by hardware at the end of bit 8 in mode 0 or in the middle of a stop bit in other modes. It must be cleared by software.

a.   If smod = 0 baud rate is Cclk/64, if smod = 1 then baud rate is Cclk/32.

Table 87. S0CON register

$$for\ bd\ (wdcon.7) = 0:$$

$$baud\ rate = \frac{2^{SMOD} * Cclk}{32} * (Timer\,1\ overflow\ rate)$$

$$for\ bd\ (wdcon.7) = 1:$$

$$baud\ rate = \frac{2^{SMOD} * Cclk}{64 * (2^{10} - s0rel)}$$

Figure 52. Equation of baud rate settings for Serial Port 0

Below is an explanation of some of the values used in :

Value	Definition
SMOD (PCON.7)	Serial Port 0 baud rate select flag
s0rel	The contents of S0REL registers (s0relh, s0rell) see chapter 12.2.3 on page 109.
bd (wdcon.7)	The MSB of WDCON register see chapter H12.2.4 on page 110

Table 88. Values of S0CON equation

12.2.2 Serial port 0 data buffer – S0BUF

Address	Reset value	Register name
0x99	0x00	S0BUF

Table 89. S0BUF register

Writing data to the S0BUF register sets data in serial output buffer and starts the transmission through Serial Port 0. Reading from the S0BUF reads data from the serial receive buffer.

12.2.3 Serial port 0 reload register – S0RELH, S0RELL

Serial Port 0 Reload register is used for Serial Port 0 baud rate generation. Only 10 bits are used, 8 bits from the S0RELL, and 2 bits from the S0RELH.

Address	Reset value	Register name
0xAA	0xD9	S0RELL
0xBA	0x03	S0RELH

Table 90. S0RELL/S0RELH register

12.2.4 Serial Port 0 baud rate select register - WDCON

The MSB of this register is used by Serial Port 0 for baud rate generation

Address	Reset value	Bit	Name	Description
0xD8	0x00	7	bd	Serial Port 0 baud rate select (in modes 1 and 3) When 1, additional internal baud rate generator is used, otherwise Timer 1 overflow is used.
		6-0		Not used

Table 91. WDCON register

13 Input/Output port (GPIO)

Six general purpose I/O lines are available on the nRF24LU1. These can be used for general I/O with selectable direction for each bit, or these lines can be used for specialized functions.

13.1 Normal IO

When `PROG=0`, the GPIO pins are controlled by the registers `P0ALT`, `P0DIR` and `P0EXP`, when `PROG=1` the GPIO pins are configured as a slave SPI port, see pins **SCSN**, **SMISO**, **SMOSI**, **SSCK** below. The `P0ALT` register selects between the default and the alternate functions for each of the six port pins when `P0EXP=0`. If `P0ALT=0` then the default function is selected, port data is set with the `P0` register, and pin direction is set with `P0DIR` register.

Address	Reset value	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bbit0
0x80	0xFF	-	-	D5	D4	D3	D2	D1	D0

Table 92. P0 register

Address	Reset value	Bit	Description
0x94	0xFF	7:6	Not used
		5:0	0: P0.x is output, 1: P0.x is input

Table 93. P0DIR register

The `P0ALT` and `P0EXP` registers are used to select alternate or expanded functions, see Table 96. on page 112 for details.

Address	Reset value	Bit	Description
0x95	0x00	7:6	Not used
		5:0	1: Alternate function, 0: General I/O, see Table 97. on page 113

Table 94. P0ALT register

Address	Reset value	Bit	Description
0xC9	0x00	7:6	Controls P0.5
		5:4	Controls P0.4
		3:2	Not used
		1:0	Controls **P0.3-P0.0**, see Table 97. on page 113 for details

Table 95. P0EXP register

The relationship between the `P0EXP` and `P0ALT` registers is shown in Table 96. on page 112.

Pin	Normal		Expanded 1	Expanded 2	Expanded 3
	Default function	Alternate			
	P0EXP[7:6]				
	00		01	10	11
	P0ALT[5]		P0ALT[5]		
	0	1	x

00XXXXX1	XXXXXX11						TCK

a. Timer0 input
b. Timer2 input
c. Timer1 input
d. Interrupt input INT0
e. GTIMER is an RTC output controlled by WGTIMER, see chapter 19.1.6 on page 151.

Table 97. Alternative functions of Port 0

14 MCU

The nRF24LU1 contains a fast 8-bit MCU, which executes the normal 8051 instruction set.

The architecture eliminates redundant bus states and implements parallel execution of fetch and execution phases. Most of the one-byte instructions are performed in one single cycle. The MCU uses 1 clock per cycle. This leads to a performance improvement rate of 8.0 (in terms of MIPS) with respect to legacy 8051 devices.

The original 8051 had a 12-clock architecture. A machine cycle needed 12 clocks and most instructions were either one or two machine cycles. Except for MUL and DIV instructions, the 8051 used either 12 or 24 clocks for each instruction. Each cycle in the 8051 also used two memory fetches. In many cases, the second fetch was a dummy, and extra clocks were wasted.

Table 98. shows the speed advantage compared to a legacy 8051. A speed advantage of 12 implies that the instruction is executed twelve times faster. The average speed advantage is 8.0. However, the real speed improvement seen in any system depends on the instruction mix.

Speed advantage	Number of instructions	Number of opcodes
24	1	1
12	27	83
9.6	2	2
8	16	38
6	44	89
4.8	1	2
4	18	31
3	2	9
Average: 8.0	Sum: 111	Sum: 255

Table 98. Speed advantage summary

14.1 Features

- Control Unit
  - ▸ 8-bit Instruction decoder
  - ▸ Reduced instruction cycle time (up to 12 times in respect to standard 80C51)
- Arithmetic-Logic Unit
  - ▸ 8-bit arithmetic and logical operations
  - ▸ Boolean manipulations
  - ▸ 8 x 8 bit multiplication and 8 / 8 bit division
- Multiplication-Division Unit
  - ▸ 16 x 16 bit multiplication
  - ▸ 32 / 16 bit and 16 / 16 bit division
  - ▸ 32-bit normalization
  - ▸ 32-bit L/R shifting
- Three 16-bit Timers/Counters
  - ▸ 80C51-like Timer 0 & 1
  - ▸ 80515-like Timer 2
- Compare/Capture Unit, dedicated to Timer 2
  - ▸ Four 16-bit Compare registers used for Pulse Width Modulation
  - ▸ Four external Capture inputs used for Pulse Width Measuring
  - ▸ 16-bit Reload register used for Pulse Generation

- Full Duplex Serial Interfaces
  - ▸ Serial 0 (80C51-like)
  - ▸ Synchronous mode, fixed baud rate
  - ▸ 8-bit UART mode, variable baud rate
  - ▸ 9-bit UART mode, fixed baud rate
  - ▸ 9-bit UART mode, variable baud rate
  - ▸ Baud Rate Generator
- Interrupt Controller
  - ▸ Four Priority Levels with 13 interrupt sources
- Memory interface
  - ▸ addresses up to 64 kB of External Program/Data Memory
  - ▸ Dual Data Pointer for fast data block transfer
- Power Management Unit
  - ▸ Power down modes: IDLE and STOP
- Interface for On-Chip Instrumentation

14.2   MCU registers
Figure 53. The MCU registers

14.3　Arithmetic Logic Unit (ALU)

The Arithmetic Logic Unit (ALU) provides 8-bit division, 8-bit multiplication, and 8-bit addition with or without carry. The ALU also provides 8-bit subtraction with borrow and some bitwise logic operations, that is, logical AND, OR, Exclusive OR or NOT.

All operations are unsigned integer operations. Additionally, the ALU can increment or decrement 8 bit registers. For accumulator only, it can rotate left or right through carry or not, swap nibbles, clear or complement bits and perform a decimal adjustment.

The ALU is handled by three registers, which are memory mapped as special function registers. Operands for operations may come from accumulator `ACC`, register `B` or from outside of the unit. The result may be stored in accumulator `ACC` or may be driven outside of the unit. The control register, that contains flags such as carry, overflow or parity, is the `PSW` (Program Status Word) register.

The nRF24LU1 also contains an on-chip co-processor MDU (Multiplication Division Unit). This unit enables 32-bit division, 16-bit multiplication, shift and normalize operations, see chapter 18 on page 146 for details.

14.4　Instruction set summary

All instructions are binary code compatible and perform the same functions as they do within the legacy 8051 processor. The following tables give a summary of instruction cycles of the MCU core.

Mnemonic	Description	Code	Bytes	Cycles
ADD A,Rn	Add register to accumulator	0x28-0x2F	1	1
ADD A,direct	Add directly addressed data to accumulator	0x25	2	2
ADD A,@Ri	Add indirectly addressed data to accumulator	0x26-0x27	1	2
ADD A,#data	Add immediate data to accumulator	0x24	2	2
ADDC A,Rn	Add register to accumulator with carry	0x38-0x3F	1	1
ADDC A, direct	Add directly addressed data to accumulator with carry	0x35	2	2
ADDC A,@Ri	Add indirectly addressed data to accumulator with carry	0x36-0x37	1	2
ADDC A,#data	Add immediate data to accumulator with carry	0x34	2	2
SUBB A,Rn	Subtract register from accumulator with borrow	0x98-0x9F	1	1
SUBB A, direct	Subtract directly addressed data from accumulator with borrow	0x95	2	2
SUBB A, @Ri	Subtract indirectly addressed data from accumulator with borrow	0x96-0x97	1	2
SUBB A, #data	Subtract immediate data from accumulator with borrow	0x94	2	2
INC A	Increment accumulator	0x04	1	1
INC Rn	Increment register	0x08-0x0F	1	2
INC direct	Increment directly addressed location	0x05	2	3
INC @Ri	Increment indirectly addressed location	0x06-0x07	1	3
INC DPTR	Increment data pointer	0xA3	1	1
DEC A	Decrement accumulator	0x14	1	1
DEC Rn	Decrement register	0x18-0x1F	1	2
DEC direct	Decrement directly addressed location	0x15	2	3
DEC @Ri	Decrement indirectly addressed location	0x16-0x17	1	3
MUL AB	Multiply A and B	0xA4	1	5
DIV	Divide A by B	0x84	1	5
DA A	Decimal adjust accumulator	0xD4	1	1

Table 99. Arithmetic operations

Mnemonic	Description	Code	Bytes	Cycles
ANL A, Rn	AND register to accumulator	0x58-0x5F	1	1
ANL A,direct	AND directly addressed data to accumulator	0x55	2	2
ANL A,@Ri	AND indirectly addressed data to accumulator	0x56-0x57	1	2
ANL A,#data	AND immediate data to accumulator	0x54	2	2
ANL direct,A	AND accumulator to directly addressed location	0x52	2	3
ANL direct,#data	AND immediate data to directly addressed location	0x53	3	4
ORL A,Rn	OR register to accumulator	0x48-0x4F	1	1
ORL A,direct	OR directly addressed data to accumulator	0x45	2	2
ORL A,@Ri	OR indirectly addressed data to accumulator	0x46-0x47	1	2
ORL A,#data	OR immediate data to accumulator	0x44	2	2
ORL direct,A	OR accumulator to directly addressed location	0x42	2	3
ORL direct,#data	OR immediate data to directly addressed location	0x43	3	4
XRL A,Rn	Exclusive OR register to accumulator	0x68-0x6F	1	1
XRL A, direct	Exclusive OR indirectly addressed data to accumulator	0x66-0x67	1	2
XRL A,@Ri	Exclusive OR indirectly addressed data to accumulator	0x66-0x67	1	2
XRL A,#data	Exclusive OR immediate data to accumulator	0x64	2	2
XRL direct,A	Exclusive OR accumulator to directly addressed location	0x62	2	3
XRL direct,#data	Exclusive OR immediate data to directly addressed location	0x63	3	4
CLR A	Clear accumulator	0xE4	1	1
CPL A	Complement accumulator	0xF4	1	1
RL A	Rotate accumulator left	0x23	1	1
RLC A	Rotate accumulator left through carry	0x33	1	1
RR A	Rotate accumulator right	0x03	1	1
RRC A	Rotate accumulator right through carry	0x13	1	1
SWAP A	Swap nibbles within the accumulator	0xC4	1	1

Table 100. Logic operations

Mnemonic	Description	Code	Bytes	Cycles
MOV A,Rn	Move register to accumulator	0xE8-0xEF	1	1
MOV A,direct	Move directly addressed data to accumulator	0xE5	2	2
MOV A,@Ri	Move indirectly addressed data to accumulator	0xE6-0xE7	1	2
MOV A,#data	Move immediate data to accumulator	0x74	2	2
MOV Rn,A	Move accumulator to register	0xF8-0xFF	1	2
MOV Rn,direct	Move directly addressed data to register	0xA8-0xAF	2	4
MOV Rn,#data	Move immediate data to register	0x78-0x7F	2	2
MOV direct,A	Move accumulator to direct	0xF5	2	3
MOV direct,Rn	Move register to direct	0x88-0x8F	2	3
MOV directl,direct2	Move directly addressed data to directly addressed location	0x85	3	4
MOV direct,@Ri	Move indirectly addressed data to directly addressed location	0x86-0x87	2	4

Mnemonic	Description	Code	Bytes	Cycles
MOV direct,#data	Move immediate data to directly addressed location	0x75	3	3
MOV @Ri,A	Move accumulator to indirectly addressed location	0xF6-0xF7	1	3
MOV @Ri,direct	Move directly addressed data to indirectly addressed location	0xA6-0xA7	2	5
MOV @Ri,#data	Move immediate data to indirectly addressed location	0x76-0x77	2	3
MOV DPTR,#data16	Load data pointer with a 16-bit immediate	0x90	3	3
MOVC A,@A+DPTR	Load accumulator with a code byte relative to DPTR	0x93	1	3
MOVC A,@A+PC	Load accumulator with a code byte relative to PC	0x83	1	3
MOVX A,@Ri	Move[a] external RAM (8-bit addr) to accumulator	0xE2-0xE3	1	3-10
MOVX A,@DPTR	Move[a] external RAM (16-bit addr) to accumulator	0xE0	1	3-10
MOVX @Ri,A	Move[a] accumulator to external RAM (8-bit addr)	0xF2-0xF3	1	4-11
MOVX @DPTR,A	Move[a] accumulator to external RAM (16-bit addr)	0xF0	1	4-11
PUSH direct	Push directly addressed data onto stack	0xC0	2	4
POP direct	Pop directly addressed location from stack	0xD0	2	3
XCH A,Rn	Exchange register with accumulator	0xC8-0xCF	1	2
XCH A,direct	Exchange directly addressed location with accumulator	0xC5	2	3
XCH A,@Ri	Exchange indirect RAM with accumulator	0xC6-0xC7	1	3
XCHD A,@Ri	Exchange low-order nibbles of indirect and accumulator	0xD6-0xD7	1	3

a. The MOVX instructions perform one of two actions depending on the state of `pmw` bit (pcon.4).

Table 101. Data transfer operations

Mnemonic	Description	Code	Bytes	Cycles
ACALL addr11	Absolute subroutine call	xxx10001b	2	6
LCALL addr16	Long subroutine call	0x12	3	6
RET	Return from subroutine	0x22	1	4
RETI	Return from interrupt	0x32	1	4
AJMP addr11	Absolute jump	xxx00001b	2	3
LJMP addr16	Long jump	0x02	3	4
SJMP rel	Short jump (relative address)	0x80	2	3
JMP @A+DPTR	Jump indirect relative to the DPTR	0x73	1	2
JZ rel	Jump if accumulator is zero	0x60	2	3
JNZ rel	Jump if accumulator is not zero	0x70	2	3
JC rel	Jump if carry flag is set	0x40	2	3
JNC rel	Jump if carry flag is not set	0x50	2	3
JB bit, rel	Jump if directly addressed bit is set	0x20	3	4
JNB bit, rel	Jump if directly addressed bit is not set	0x30	3	4

Mnemonic	Description	Code	Bytes	Cycles
JBC bit, rel	Jump if directly addressed bit is set and clear bit	0x10	3	4
CJNE A, direct, rel	Compare directly addressed data to accumulator and jump if not equal	0xB5	3	4
CJNE A,#data,rel	Compare immediate data to accumulator and jump if not equal	0xB4	3	4
CJNE Rn, #data, rel	Compare immediate data to register and jump if not equal	0xB8-0xBF	3	4
CJNE @Ri, #data, rel	Compare immediate data to indirect addressed value and jump if not equal	0xB6-B7	3	4
DJNZ Rn, rel	Decrement register and jump if not zero	0xD8-DF	2	3
DJNZ direct, rel	Decrement directly addressed location and jump if not zero	0xD5	3	4
NOP	No operation	0x00	1	1

Table 102. Program branches

Mnemonic	Description	Code	Bytes	Cycles
CLR C	Clear carry flag	0xC3	1	1
CLR bit	Clear directly addressed bit	0xC2	2	3
SETB C	Set carry flag	0xD3	1	1
SETB bit	Set directly addressed bit	0xD2	2	3
CPL C	Complement carry flag	0xB3	1	1
CPL bit	Complement directly addressed bit	0xB2	2	3
ANL C,bit	AND directly addressed bit to carry flag	0x82	2	2
ANL C,/bit	AND complement of directly addressed bit to carry	0xB0	2	2
ORL C,bit	OR directly addressed bit to carry flag	0x72	2	2
ORL C,/bit	OR complement of directly addressed bit to carry	0xA0	2	2
MOV C,bit	Move directly addressed bit to carry flag	0xA2	2	2
MOV bit,C	Move carry flag to directly addressed bit	0x92	2	3

Table 104. Opcode map

15   Memory and I/O organization

The MCU has a 64 kbytes address space for code and data, an area of 256 byte for internal data (IRAM), and an area of 128 byte for Special Function Registers (SFR).

The nRF24LU1 has 16 kbytes of flash program memory, 2 kbytes of SRAM data memory and a dedicated internal RAM of 256 byte for MCU internal data, see Figure 54. To allow erase and write flash operations, the MCU must run the sequence described in section 17.3.1.

In addition, an area of 2 kbytes is reserved for the USB buffer RAM and the USB configuration registers.

0xFFFF	
0xC7FF	USB (RAM) (2 KB)
0xC000	
0x87FF	Data (RAM) (2 KB)
0x8000	
0x3FFF	Program/Data (Flash) Accessible with movc and movx (16KB)
0x0000	

IRAM

0xFF — Accessible by indirect addressing only
0x80
0x7F — Accessible by direct and indirect addressing
0x00

SFR

0xFF — Accessible by direct addressing only
0x80

Special Funtion Registers
Note: In a program running in a protected flash area, movc may not be used to access addresses 0x00 to 0x03.

Table 106. Special Function Registers reset values

15.1.3   Accumulator - ACC

Accumulator is used by most of the MCU instructions to hold the operand and to store the result of an operation.

Note: The mnemonics for accumulator specific instructions refer to accumulator as A, not ACC.

Address	Reset value	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
0xE0	0x00	acc.7	acc.6	acc.5	acc.4	acc.3	acc.2	acc.1	acc.0

Table 107. ACC register

15.1.4   B register – B

The B register is used during multiplying and division instructions. It can also be used as a scratch-pad register to hold temporary data.

Address	Reset value	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
0xF0	0x00	b.7	b.6	b.5	b.4	b.3	b.2	b.1	b.0

Table 108. B register

15.1.5 Program Status Word register - PSW

The `PSW` register contains status bits that reflect the current state of the MCU.

Address	Reset value	Bit	Name	Description
0xD0	0x00	7	cy	Carry flag: Carry bit in arithmetic operations and accumulator for Boolean operations.
		6	ac	Auxiliary Carry flag: Set if there is a carry-out from 3rd bit of Accumulator in BCD operations
		5	f0	General purpose flag 0
		4-3	rs	Register bank select, bank 0..3 (0x00-0x07, 0x08-0x0f, 0x10-0x17, 0x18-0x1f)
		2	ov	Overflow flag: Set if overflow in Accumulator during arithmetic operations
		1	f1	General purpose flag 1
		0	p	Parity flag: Set if odd number of '1' in ACC.

Table 109. PSW register

Note: The Parity bit can only be modified by hardware in the ACC register state.

15.1.6 Stack Pointer – SP

This register points to the top of the stack in internal data memory space. It is used to store the return address of a program before executing an interrupt routine or subprograms. The `SP` register is incremented before executing PUSH or CALL instruction and it is decremented after executing POP or RET(I) instruction (it always points to the top of the stack).

Address	Reset value	Register name
0x81	0x07	SP

Table 110. SP register

15.1.7 Data Pointer – DPH, DPL

Address	Reset value	Register name
0x82	0x00	DPL
0X83	0x00	DPH

Table 111. Data Pointer register (DPH:DPL)

The Data Pointer registers can be accessed through `DPL` and `DPH`. The actual data pointer is selected by `DPS` register.

The Data Pointer registers are intended to hold a 16-bit address in the indirect addressing mode used by MOVX (move external memory), MOVC (move program memory) or JMP (computed branch) instructions. They may be manipulated as 16-bit register or as two separate 8-bit registers. `DPH` holds a higher byte and `DPL` holds a lower byte of an indirect address.

These registers are used to access external code or data space (for example, MOVC A, @A+DPTR or MOV A, @DPTR).

15.1.8 Data Pointer 1 – DPH1, DPL1

Address	Register name
0x84	DPL1
0X85	DPH1

Table 112. Data Pointer 1 register (DPH1:DPL1)

The Data Pointer register 1 can be accessed through DPL1 and DPH1. The actual data pointer is selected by DPS register.

These registers are intended to hold a 16-bit address in the indirect addressing mode used by MOVX (move external memory), MOVC (move program memory) or JMP (computed branch) instructions. They can be manipulated as a 16-bit register or as two separate 8-bit registers. DPH1 holds a higher byte and DPL1 holds a lower byte of an indirect address.

These registers are used to access external code or data space (for example, MOVC A,@A+DPTR or MOV A,@DPTR respectively).

The Data Pointer 1 is an extension to the standard 8051 architecture to speed up block data transfers.

15.1.9 Data Pointer Select register – DPS

The MCU contains two Data Pointer registers. Both Data Pointer registers can be used as 16-bits address source for indirect addressing. The DPS register serves for selecting the active data pointer register.

Address	Reset value	Bit	Name	Description
0x92	0x00	7:1	-	Not used
		0	dps	Data Pointer Select. 0: select DPH:DPL, 1: select DPH1:DPL1

Table 113. DPS register

16 Random Access Memory (RAM)

The nRF24LU1 contains two separate RAM blocks. These blocks are used to save temporary data or programs.

The RAM blocks are 256x8 IRAM bits and 2048x8 bits.

> **Note:** The information in these blocks is lost when power to the device is removed.

As described in , the RAM resides in different maps, that is, different instructions are used to access them.

The smallest RAM-block (256 bytes) resides in the "internal" RAM-area, called IRAM, and contains scratch-pad data, subroutine stacks, register files, and so on.

> **Note:** The lower 128 bytes can be addressed direct or indirectly, while the upper 128 bytes can only be accessed using indirect addressing.

The largest RAM (2048 bytes) resides in the XDATA space and is a fixed block located from address 0x8000 to 0x87FF. This block is used for data or program code.

16.1 Cycle control

The MCU has a programmable SFR register that controls timing to on-chip memory. Since this memory is fast, the default values are recommended. If a program frequently accesses XDATA then stretch control can be set to three zeros (000) to improve performance.

Address	Reset value	Bit	Description
0x8E	0x01	7	Not used
		6-4	Program memory wait state control 000: No wait-states (default at power-up) Other values are reserved and should not be used
		3	Not used
		2-0	External data memory stretch control. 001: One stretch cycle (default) Other values are reserved and should not be used

Table 114. CKCON register

17   Flash Memory

This section describes the operation of the embedded flash memory. You can read, program and erase the memory from the SPI slave interface. You can read the memory from the MCU and under special circumstances the MCU can perform write and erase operations, for instance, when performing a firmware upgrade through the USB interface (this requires that special firmware is installed). You can also program the flash memory through the USB by using the USB bootloader.

17.1   Features

- 16k Flash memory
- 32 pages of main block + 1 infopage
- Page size 512 bytes
- Endurance minimum 1000 write/erase cycles
- Direct SPI programmable
- Read and write accessible from MCU
- Configurable write protect
- Configurable readback protect

The 16 kbytes flash memory is divided into two blocks, the main block and the information block (infopage) with only one page of flash array. The page size of the flash memory is 512 byte.

At the chip interface the flash behaves as an SPI programmable flash memory. All configuration and setup of the behavior during normal mode (that is, when MCU is active and running) is defined through the SPI and the configuration data is stored in the infopage. During the chip reset/start-up sequence the configuration data is read and stored in a set of registers that control flash memory behavior.
Figure 55. Flash memory organization

The main block of flash memory can be configured through the SPI (Figure 55.) in the following ways:

- Unprotected program memory; can be read, written and erased through the SPI and by the MCU. With no configuration the whole main block is unprotected memory.
- Protected program memory; can be read, written and erased through the SPI but only read by the MCU. Any number of pages can be configured as protected memory.
- Data memory; can be read, written and erased through the SPI and by the MCU. Two data pages may be enabled. If enabled, the number of protected pages are reduced by two.

You can program the infopage through the SPI only, with the MCU having only read access to the infopage.

> **Note:** You can write to a flash byte only once between each erase. To rewrite a flash byte, a page (or full) erase must run first. This sets the value of all erased bytes to 0xFF.

17.1.1 Functional description

17.1.1.1 Infopage content

The content of the infopage is given in Table 115. below:

Infopage data	Size	Address	Comment
Reserved	32 bytes	0x00	Reserved. Do not delete.
Page address at start of protected area (that is, number of unprotected pages)	1 byte	0x20	Read out during reset/start-up sequence of the chip to register FPCR Byte value: 0xFF: all pages are unprotected Other value: page address
Encoded DAEN, Enable flash data memory	1 byte	0x21	Read out during reset/start-up sequence of the chip. Byte value: 0xFF: no data memory, DAEN=0 Other value: data memory exists, DAEN=1
Readback blocking byte for infopage	1 byte	0x22	Read out during reset/start-up sequence of chip. Byte value: 0xFF: RDISIP=0 Other value: RDISIP=1 Note: This also blocks readout of chip identification.
Readback blocking byte for main block	1 byte	0x23	Read out during reset/start-up sequence of chip. Byte value: 0xFF: RDISMB=0 Other value: RDISMB=1
Enable debug	1 byte	0x24	Read out during reset/start-up sequence of chip. Byte value: 0xFF: DBG=0 Other value: DBG=1 if RDISMB=0, enable debug, See chapter 22 on page 162
Reserved	219 bytes	0x25	Reserved, do not use.
For user data	256 bytes	0x100	Free to use.

> **Note:** See also Table 116..

Table 115. Infopage content

17.1.1.2 Registers to control flash operations

Addr	Reset value	Bit	Name	RW	Function
0xF8	N/A				FSR – Flash Status Register
		7	DBG	RW	1: Debug enabled, 0: Debug disabled, can be set by MCU
		6	STP	R	1: Start from protected program memory
		5	WEN	RW	Write enable. 1: enable
		4	RDYN	R	Flash interface ready. 0: ready
		3	INFEN	RW	Infopage enable. 1: enable
		2	RDISMB	R	SPI read-back disable of main block. 1: read back disable
		1	RDISIP	R	SPI read-back disable of infopage. 1: read back disable
		0	-		Reserved, read as 0.
0xF9	N/A				FPCR – Flash Protect Configuration Register
		7	DAEN	R	1: Two pages of data memory enabled, 0: no data memory enabled.
		6:0	NUPP	R	Number of unprotected pages.
0xFA	0x00				FCR – Flash Command Register
		7:5	-	R	Not used
		4:0	EPA	RW	Byte value < 32: Erase page address, otherwise used for secure MCU flash write, see section 17.3.1 on page 132.

Table 116. FSR, FPCR and FCR registers

17.2 Brown-out

There is an on-chip brown-out detector that ensures that the write operation is aborted safely and that the chip restarts from reset if there is a power disturbance during a flash write operation.

17.3 Flash programming from the MCU

This section describes how you can write and erase the flash memory using the MCU.

17.3.1 MCU write and erase of the main block

When a flash write is initiated, the MCU is halted for 740 clock cycles (46µs @16Mhz) for each byte written. When a page erase is initiated, the MCU can be halted for up to 360,000 clock cycles (22.5 ms @16Mhz). During this time the MCU does not respond to any interrupts. Firmware must assure that page erase does not interfere with normal operation of the nRF24LU1.

The MCU can perform erase page and write operations to the unprotected part and the data part of the flash main block. To prevent unwanted/harmful erase and write operations a security mechanism is implemented.

To allow erase and write flash operations the MCU must run the following sequence:

1. Write 0xAA to the FCR register. This starts an internal 7 bit down counter. The counter counts down from 127 to 0.
2. Before the count down period has expired (8 µs @16Mhz), write 0x55 to the FCR. This restarts the internal 7 bit down counter. The counter counts down from 127 to 0. In the count down period (8 µs) the WEN bit in the FSR register is writeable from the MCU.

3. Set `WEN` in `FSR` register high before count down period has expired.
4. The flash is now open for erase and write from the MCU until `WEN` is set low again. `WEN` can be set low directly (no security mechanism applies).
5. To erase a page, write page address (range 0-31) to the `FCR` register. Bytes are written individually (there is no auto increment) to the flash using the specific memory address. When the programming code executes from the flash erase or write operation is self timed and the CPU stops until the operation is finished. If the programming code executes from the XDATA RAM the code must wait until the operation has finished. This can be done either by polling the `RDYN` bit in the `FSR` register to go low or by a wait loop. Do not set `WEN` low before the write or erase operation is finished. Memory address is identical to the flash address, see Chapter 15 on page 122 for memory mapping.

17.3.2   Boot, start of code execution

If the STP bit in the `FSR` register is high the MCU starts a program execution from the lowest address in the protected part of the flash memory (FPCR[6:0]<<9). If the STP bit is low (as it is in a normal case) the MCU starts an execution from address "0" of the flash memory.

> **Note:** There is only one set of interrupt vectors (see Table 135.) and they always point to the first page of flash memory, regardless of whether the page is defined as protected or unprotected memory. So, if a program is placed in the protected part of flash memory starting at a higher page, the corresponding interrupt vectors still point to the unprotected part of memory. Unless the implications of this are clearly understood, it is recommended not to use interrupt in programs intended to run from the protected area.

The value of the STP bit is decided in the chip start-up sequence. If the content of the 16 highest addresses of the flash memory (main block) have an odd number of 1's then STP is set high. Otherwise, STP is set low because the flash is configured with a data area in the two upper pages. If the data area is not enabled the STP bit is always low. This mechanism is used to obtain a safe upgrade for the unprotected area of the flash.

Here is an example of this mechanism in use:

- The application is running in an unprotected area and the program doing the upgrade resides in a protected area.
- You must configure flash with DAEN=1, Data AREA Enabled, to allow firmware control over the STP bit.
- The host initiates a firmware upgrade over the USB interface.
- Set WEN as described in section 17.3.1 on page 132.
- A bit in one of the 16 highest addressed bytes is programmed to 0.
- You can now restart the system. The system restarts from the protected area.
- You can now perform erase and write operations safely in the unprotected area, that is, you can update the unprotected area through the USB interface.
  In case of a power failure or a restart the MCU starts an execution in the protected area.
- When the upgrade is finished a new bit in one of the 16 highest addressed bytes is programmed to 0 which gives an even number of 1s in these bytes, implying STP=0, after next reset.
- You can now restart the system, and it restarts from the unprotected area.

> **Note:** For program in protected area, see the restriction for movc in Figure 54. on page 122

17.4   Flash programming through USB

The nRF24LU1 bootloader allows you to program the nRF24LU1 through the USB interface. The boot-loader is pre-programmed into the nRF24LU1 flash memory and automatically starts when power is applied. After start-up the bootloader copies the flash programming code to the internal SRAM from where the complete flash memory can be programmed.

The bootloader occupies the topmost 2K bytes (KB) of the flash and is not deleted unless the user program extends into this area. If the program is larger than 14KB the bootloader is overwritten and lost.

In addition to the topmost 2 KB of the flash, the bootloader also uses the 3 byte reset vector at address 0. If your application needs to re-execute the bootloader; you must restore the reset vector so that the boot-loader executes after power on reset.

17.4.1   Flash Layout

The 16 KB flash is divided into 32 pages of 512 bytes each. Since the maximum USB packet size is 64 bytes the bootloader divides each flash page into 8 blocks of 64 bytes each as shown in Figure 56.
Figure 56. Relation between address, pages and blocks

17.4.2 USB Protocol

nRF24LU1 begins enumerating when connected to a USB host and is available to the operating system. A driver, or application, communicating with the bootloader must use the following parameters:

USB parameters	Value	Comment
VID (Vendor Identification)	0x1915	
PID (Product Identification)	0x0101	
IN Endpoint address	0x81	Endpoint 1 IN Bulk
OUT Endpoint address	0x01	Endpoint 1 OUT Bulk

Table 117. Driver/application USB parameters for communication with bootloader

The USB host communicates with the bootloader by writing commands to the IN endpoint. All USB commands to the bootloader start with a 1 byte identifier (cmd id) and return a packet, see sections 17.4.2.1, 17.4.2.2, 17.4.2.3 and 17.4.2.4. If the command takes parameters, the parameters are written as 1 byte after the 1 byte identifier, for example, command 0x02 takes the parameter pn. Each command returns a value that must be read from the OUT endpoint.

17.4.2.1 Firmware version (cmd 0x01)

Figure 57. Command 0x01

This command returns the firmware version of the bootloader. hb is the major version number and lb is the minor version number. For example, when hb=0x01 and lb=0x00 the version is 1.0.

17.4.2.2 Flash page write (cmd 0x02)

This command is sent to the bootloader to start writing a flash page to the page indicated by the parameter pn. After this command is completed the host must send the 8 blocks that constitutes the page. This is done by sending 64 byte packets to the USB IN endpoint with the contents of the block. The bootloader responds with a one-byte packet (containing 0x00) after each packet has been sent.
Figure 58. Command 0x02

17.4.2.3 Read flash block (cmd 0x03)

This command is sent by the host to read one of the 64 byte flash blocks. The block is indicated by the parameter bn.

| 0x03 | bn | Returns: | b0 | ... | b63 |

Figure 59. Command 0x03

17.4.2.4 Flash page erase (cmd 0x04)

This command is used mainly for debugging purposes since the Flash Page Write command above automatically erases the page if needed prior to programming. Using this command erases page pn.

| 0x04 | pn | Returns: | 0 |

Figure 60. Command 0x04

17.5 Flash programming through SPI

The on-chip flash is designed to interface a standard SPI device for programming. The interface uses an 8 bit instruction register and a set of instructions/commands to program and configure the flash memory.

17.5.1 SPI commands

To allow access through the SPI the external **PROG** pin must be set high during all flash operation commands. After activation of the **PROG** pin you must wait at least 1.5 ms before you input the first flash command. When the **PROG** pin is set, the **GPIO** pins are automatically configured as slave SPI (see chapter 13 on page 111. Further description of SPI slave is found in chapter 10 on page 98).

Command	Command format	Command operation
WREN	0x06	Set flash write enable, FSR bit5 (WEN)
WRDIS	0x04	Reset flash write enable, FSR bit5 (WEN)
RDSR	0x05	Read Flash Status Register (FSR)
WRSR	0x01	Write Flash Status Register (FSR). (The DBG bit in FSR can be set by the MCU but not through the SPI).
READ	0x03	Read data from flash
PROGRAM	0x02	Write data to flash
ERASE PAGE	0x52	Erase addressed page
ERASE ALL	0x62	Erase all pages
RDFPCR	0x89	Read Flash Protect Configuration Register (FPCR)
RDISIP	0x84	Set flash infopage read-back disable, FSR bit1 (RDISIP)
RDISMB	0x85	Set flash main block read-back disable, FSR bit2 (RDISMB)
ENDEBUG	0x86	Enable debugger through JTAG-pins, see chapter 22 on page 162 for details, FSR bit7 (DBG)

Table 118. Flash SPI operation commands
Figure 61. SPI read operation.
Figure 62. SPI write operation.

An SPI command always starts with the external master sending a command byte to the flash slave, followed by a variable number of address and data bytes. The number of address and data bytes are specific to each command, as described below. In Figure 61. and Figure 62. above Cn is the SPI Command Bit and Dn is the Data Bit (note: LSByte to MSByte, MSBit in each byte first).

17.5.1.1   Write enable (WREN)

Set Write ENable latch (WEN in FSR), bit 5 in the status register. The device powers up in write disable state. Each write and erase instruction must be enabled with a WREN command. This is a single byte command with no data.

17.5.1.2   Write disable (WRDIS)

Reset Write ENable latch (WEN in FSR). This is a single byte command with no data.

17.5.1.3   Read status register (RDSR)

Read Flash Status Register (FSR) command, which consists of a command byte and a variable number of data bytes, for optional re-read.

17.5.1.4   Write status register (WRSR)

Write Flash Status Register (FSR) command, which consists of a command byte and one data byte.

17.5.1.5   READ

Reading the flash content through the MISO line requires the following sequence:

1.   The CSN line is activated (that is, pulled low) to enable/ activate the SPI slave.

2. The READ command is transmitted through the MOSI line followed by the two byte address to the byte to be read.
3. The addressed data byte is shifted out on the MISO line.

If the CSN line is kept active after the first byte is read out the read command can be extended, the address is auto incremented and data continues to be shifted out. The internal address counter rolls over when the highest address is reached, allowing the complete memory to be read in one continuous read command.

A readback of the flash content is only possible if read disable bits (RDISMB and RDISIP) in the FSR register are not set.

17.5.1.6   PROGRAM

Writing the flash content through the MISO line requires the following sequence:

1. Enable the device for writing using the WREN command.
2. The CSN line is pulled low to enable the SPI slave.
3. The PROGRAM command is sent on the MOSI line followed by the two byte address (address of the first byte) and the data to be programmed/ written.
4. The on-chip driven program sequence is started when you set the CSN pin high/ deactivated.
5. During the program sequence all SPI commands are ignored except the RDSR command.

The CSN line can be kept active to write up to 256 bytes (with address auto increment) in one PROGRAM command. The first byte can be anywhere in a page. A byte can not be reprogrammed without erasing the whole page.

The device returns to write disable after completion of a PROGRAM command.

17.5.1.7   ERASE PAGE

To erase the content of one flash page, the following sequence is required:

1. Enable the device for writing using the WREN command.
2. The CSN line is pulled low to enable the SPI slave.
3. The ERASE PAGE command is sent on the MOSI line followed by the page number (0-31) to be erased.
4. The on-chip driven erase sequence is started when the CSN pin is set high.
5. During the erase sequence all SPI commands are ignored except the RDSR command.

The infopage is erased by this command if INFEN (bit3 in FSR) is set. The device returns to write disable after completion of an ERASE PAGE command.

17.5.1.8   ERASE ALL

To erase all flash content, the following sequence is required:

1. Enable the device for writing using the WREN command.
2. The CSN line is pulled low to enable the SPI slave.
3. The ERASE ALL command is sent on the MOSI line.
4. The on-chip driven erase sequence is started when the CSN pin is set high.
5. During the erase sequence all SPI commands are ignored except the RDSR command.

If INFEN (bit 3 in FSR) is set high before execution of the ERASE_ALL command, both the infopage and the MainBlock are erased, otherwise only the MainBlock is erased.

The device returns to write disable after completion of an ERASE ALL command.

17.5.1.9 Read Flash Protect Configuration register (RDFPCR)

Read the Flash Protect Configuration Register (FPCR) command. This is a two byte command consisting of a command byte and one data byte.

17.5.1.10 Read Disable Infopage (RDISIP)

Set Flash infopage readback disable and clear byte 0x22 in flash infopage. This is a single byte command with no data.

17.5.1.11 Read Disable MainBlock (RDISMB)

Set Flash MainBlock readback disable and clear byte 0x23 in flash infopage. This is a single byte command with no data.

17.5.1.12 Enable Debugger (ENDEBUG)

Enable the on-chip hardware debugger and clear byte 0x24 in flash infopage. This is a single byte command with no data.

17.5.1.13 SPI Readback disable

A mechanism to prevent readback over the SPI bus is implemented. Two bytes of the infopage are reserved for this. The infopage and MainBlock each have their own readback disable signal, RDISIP and RDISMB respectively. The signal values are available in the FSR register in bits 2:1. The infopage content is checked whenever the chip is started or restarted. If byte 0x22 of infopage==0xFF, RDISIP=0, otherwise RDISIP=1. If byte 0x23 of infopage==0xFF, RDISMB=0, otherwise RDISMB=1.

The infopage bytes may be written once, (by using command SPI commands RDISIP or RDISMB) which enables the readback disable function. Until the flash memory is erased the readback cannot be enabled again. RDISMB=1 inhibits page erase and write to flash (both MainBlock and infopage), but erase all is always allowed, it is also the only way to clear RDISMB.

17.5.2 Standalone programming requirements

When programming the nRF24LU1 in a standalone flash/EEPROM/MCU programmer, an adapter board (or socket assembly) with capacitors and resistors and possibly an oscillator are required. The following table describes how the device pins are used:

Signal	Pins	Disposition	Further information
VDD	1, 3, 9, 19, 24, 27	Connect together to supply and decouple	See 17.5.2.2
VBUS	3	Open	See 17.5.2.2
D+	4	Leave open	
D-	5	Leave open	
VSS	6, 12, 17, 18, 23, 26, 30	Connect to ground net (plane)	See 17.5.2.2

Signal	Pins	Disposition	Further information
PROG	7	Connect to pin electronics or strap to VDD	See 2.2.4
RESET	8	Connect to pin electronics or strap to VDD	See 2.2.7
SCK	10	Connect to pin electronics (nRF24LU1 in)	See 17.5.1
MOSI	11	Connect to pin electronics (nRF24LU1 in)	See 17.5.1
MISO	13	Connect to pin electronics (nRF24LU1 out)	See 17.5.1
CSN	14	Connect to pin electronics (nRF24LU1 in)	See 17.5.1
P0.4	15	Leave open	
P0.5	16	Leave open	
VDD_PA	20	Leave open	
ANT1	21	Leave open	
ANT2	22	Leave open	
IREF	25	Leave open	
DEC1	28	Leave open	
DEC2	29	Decouple to VSS	See 17.5.2.2
XC2	31	leave open (optionally connect to XTAL)	See 17.5.2.1
XC1	32	Connect to clock source	See 17.5.2.1

Table 119. Device pins

17.5.2.1 Clock requirements

The XC1 requires a clock between 9MHz and 16MHz during the entire programming sequence. The programming speed is directly proportional to the speed of the clock so, we recommend a clock speed of 16MHz +/- 60ppm. The clock source can be a crystal between `xc1` and `xc2` or an external clock source connected to the `xc1` pin:

- From an oscillator module on the adapter board or a pin driver in the programmer.
  - Required amplitude is at least 0.5V p-p, maximum 3.3V p-p.
  - Waveform is sine or square.
  - Required duty cycle is 40% to 60% (V/2 in the sine case).
Figure 63. External clock source

- From a crystal between XC1 (pin 32) and XC2 (pin 31)
  - ▸ See chapter 23 on page 163 for oscillator circuitry details.
  - ▸ Make sure the socket solution does not add significant parasitic to the circuit.
Figure 64. Clock source from a crystal between XC1 and XC2 pins

17.5.2.2   Power supply requirements

All VSS pins should be well connected to the adapter board, preferably using a ground plan. All VDD pins should be connected together and decoupled with at least three capacitors, 10nF each, to VSS. The `DEC2` pin should be decoupled with 33nF to VSS.

Using 3.3V supply (preferred)

Leave the `VBUS` pin open and connect a 3.3V +/- 5% power supply to the VDD pins.

17.5.2.3   Signal pin requirements

SPI Port

The pins `CSN`, `SCK` and `MOSI` must be driven by programmer pin electronics. All write operations to the FLASH are controlled by these three signals. The pin `MISO` is an output of the nRF24LU1 that must be read to validate flash contents, and can be read to check status during write or erase operations.

The clock frequency of the SPI port is not correlated to the XC1 clock (it does not need to be synchronous). The SPI data signals have no defined relation to the XC1 clock (can be any phase). For more information see .

Control pins PROG and RESET

If power on sequence is clean (that is, nRF24LU1 is well seated when power is ramped and power ramp is monotonous), the program and reset signals may be strapped to VDD. However, if possible, these signals should be controlled by pin drivers so that they are independent of power ramp quality.

17.5.3   In circuit programming over SPI

You can program a finished PCB with nRF24LU1 that has all parts mounted. There are similar requirements to a standalone programmer with the following exceptions:

- All pins must be connected according to application requirements.
- `PROG` pin needs a pull-down on the PCB.
- `PROG` pin should be under control of the programmer over the edge of the PCB or through a pogo pin.
- `RESET` pin needs a pull-up on the PCB.
- `RESET` pin should be under control of the programmer over the edge of the PCB or through a pogo pin (to restart device after programming if required).
- The SPI input pins (`CSN`, `SCK`, `MOSI`) should be under control of the programmer over the edge of the PCB or through a pogo pin.
- The SPI output pin (`MISO`) should be readable by programmer over the edge of the PCB or through a pogo pin.
- The applications use of the SPI port pins should not conflict with the use of these pins as a SPI port.
- nRF24LU1 can be powered effectively by a 5V connected to VBUS (over USB plug or pogo pin) or by a 3.3V +/- 5% connected to VDD over the edge of the PCB or through a pogo pin.

17.5.4   SPI programming sequences

The details of SPI timing are described in section 10.3 on page 99. With limit track length (and other loading on `MISO`) it is possible to operate the SPI up to 8MHz. Reducing that to 4MHz (or even 2MHz) does not significantly impact the overall programming time.

The sequences of command and data in an SPI command are found in Figure 61. on page 137 and Figure 62. on page 137. In these figures only 2 bytes of data are shown. Typically for read and write data transfers the block should be as long as possible (64 to 256 data bytes gives the best performance).

The typical production line sequence of commands is:

1. Pulse `RESET` pin low and return to high.
2. Pull `PROG` pin high and wait for 2ms.
3. Issue `WREN` command
4. Issue `ERASE_ALL` command
5. Wait for the `ERASE_ALL` command to finish (this takes 360,000 clock cycles (XC1) after the positive edge of CSN).
6. Repeat the following 64 times:
    ▸ Issue `WREN` command
    ▸ Issue `PROGRAM` command followed by the next address and then the next 256 data bytes.
    ▸ Wait until the `PROGRAM` command is finished (this is 256 + 1 times 365 clock cycles (XC1) after the positive edge of CSN).
7. Repeat the following 64 times:
    ▸ Issue `READ` command followed by next address then read out 256 bytes on `MISO`
    ▸ Compare read bytes against expected

The following are optional steps that update the infopage fields:

8. Issue `WFSR` to set `INFEN` bit to 1.

IF "Offset to start of protected area" is specified (not equal to 0xFF):

9. Issue SPI command WREN
10. Issue SPI command PROGRAM with address 0x0020 followed by the offset byte
11. Wait until PROGRAM command is finished

IF "Enable data area" is specified:

12. Issue SPI command WREN
13. Issue SPI command PROGRAM with address 0x0021 followed by a byte that is not 0xFF
14. Wait until PROGRAM command has completed (this is 365 clock cycles (XC1) after the positive edge of CSN).

IF "Disable Program readback" is specified:

15. Issue SPI command RDISMB
16. Wait until PROGRAM command has completed (this is 365 clock cycles (XC1) after the positive edge of CSN).

IF "Disable infopage readback" is specified:

17. Issue SPI command RDISIP
18. Wait until PROGRAM command has completed (This is 365 clock cycles (XC1) after the positive edge of CSN).

> **Note:** The completion of the `ERASE_ALL` and/or the `PROGRAM` command may be ensured by waiting the specified amount of time, or alternatively repeatedly issuing `RDSR` commands until the `RDYN` bit reads back as 0.

17.5.4.1   Erasing the infopage

Our devices have all user defined fields of the infopage pre-erased. The above programming sequence does not erase the infopage. If infopage needs to be erased due to re-programming of a part, step 3 in the above procedure should be modified to:

3. Issue `WFSR` to set INFEN bit to 1
4. Issue `READ` with address 0x0000 and read and save 32 bytes
5. Issue `WREN`

And step 5 should be modified to:

5. Wait until `ERASE_ALL` command is finished (this will be 360,000 clock cycles (XC1) after the positive edge of CSN).
6. Issue `WREN`
7. Issue `PROGRAM` followed by the 32 bytes saved in step 4 above.
8. Wait until the `PROGRAM` command is finished. This will be 32 + 1 times 370 clock cycles (XC1) after the positive edge of CSN.
9. Issue the `WFSR` command to set `INFEN` bit to 0.

   Note: The completion of the `ERASE_ALL` and/or the `PROGRAM` command may be ensured by waiting the specified amount of time, or alternatively repeatedly issuing `RDSR` commands until the `RDYN` bit reads back as 0.

18   MDU – Multiply Divide Unit

The MDU – Multiplication Division Unit, is an on-chip arithmetic co-processor which enables the MCU to perform additional extended arithmetic operations like 32-bit division, 16-bit multiplication, shift and, normalize operations. All operations are unsigned integer operations.

The MDU is handled by seven registers, which are memory mapped as Special Function Registers. The arithmetic unit allows concurrent operations to be performed independent of the MCU's activity.

Operands and results are stored in MD0 .. MD5 registers. The module is controlled by the ARCON register. Any calculation of the MDU overwrites its operands.

18.1   Features

The MDU is controlled by the SFR registers MD0 .. MD5 and ARCON.

18.2   Functional description

The MD0 .. MD5 are registers used in the MDU operation.

Address	Register name
0xE9	MD0
0xEA	MD1
0xEB	MD2
0xEC	MD3
0xED	MD4
0xC7	MD5

Table 120. Multiplication/Division registers MD0..MD5

The ARCON register controls the operation of MDU and informs you about its current state.

Address	Reset value	Bit	Name	Description
0xEF	0x00	7	mdef	MDU Error flag MDEF. Indicates an improperly performed operation (when one of the arithmetic operations has been restarted or interrupted by a new operation).
		6	mdov	MDU Overflow flag MDOV. Overflow occurrence in the MDU operation.
		5	slr	Shift direction, 0: shift left, 1: shift right.
		4-0	sc	Shift counter. When set to '0's, normalize operation is selected. After normalization, the "sc.0" … "sc.4" contains the number of normalizing shifts performed. Shift operation is selected when at least one of these bits is set high. The number of shifts performed is determined by the number written to "sc.4".., "sc.0", where "sc.4" is the MSB.

Table 121. ARCON register

The operation of the MDU consists of the following phases:

18.2.1 a) Loading the MDx registers

The type of calculation the MDU has to perform is selected in accordance with the order in which the MDx registers are written.

Operation	32 bit/16 bit		16 bit / 16 bit		16 bit x 16 bit		Shift/normalize	
first write	MD0 (lsb) MD1 MD2 MD3 (msb)	Dividend	MD0 (lsb) MD1 (msb)	Dividend	MD0 (lsb)	Num1	MD0 (lsb) MD1 MD2 MD3 (msb)	Number
					MD4 (lsb)	Num2		
	MD4 (lsb) MD5 (msb)	Ddivisor	MD4 (lsb) MD5 (msb)	Ddivisor	MD1 (msb)	Num1		
last write					MD5 (msb)	Num2	ARCON	

Table 122. MDU registers write sequence

1. Write MD0 to start any operation.
2. Write operations, as shown in Table 122. to determine appropriate MDU operation.
3. Write (to MD5 or ARCON) starts selected operation.

The SFR Control detects some of the above sequences and passes control to the MDU. When a write access occurs to MD2 or MD3 between write accesses to MD0 and finally to MD5, then a 32/16 bit division is selected.

When a write access to MD4 or MD1 occurs before writing to MD5, then a 16/16 bit division or 16x16 bit multiplication is selected. Writing to MD4 selects 16/16 bit division and writing to MD1 selects 16x16 bit multiplication, that is, Num1 x Num2.

18.2.2 b) Executing calculation

During executing operation, the MDU works on its own in parallel with the MCU.

Operation	Number of clock cycles	
Division 32bit/16bit	17 clock cycles	
Division 16bit/16bit	9 clock cycles	
Multiplication	11 clock cycles	
Shift	min. 3 clock cycles (sc = 01h)	max 18 clock cycles (sc = 1Fh)
Normalize	min. 4 clock cycles (sc <- 01h)	max 19 clock cycles (sc <- 1Fh)

Table 123. MDU operations execution times

18.2.3   c) Reading the result from the MDx registers

Operation	32 bit/16 bit		16 bit / 16 bit		16 bit x 16 bit		Shift/normalize	
first read	MD0 (lsb) MD1 MD2 MD3 (msb)	Quotient	MD0 (lsb) MD1 (msb)	Quotient	MD0 (lsb) MD1 MD2	Product	MD0 (lsb) MD1 MD2	Number
last read	MD4 (lsb) MD5 (msb)	Remainder	MD4 (lsb) MD5 (msb)	Remainder	MD3 (msb)		MD3 (msb)	

Table 124. MDU registers read sequence

The Read out sequence of the first MDx registers is not critical but the last read (from MD5 - division and MD3 - multiplication, shift or normalize) determines the end of a whole calculation (end of phase three).

18.2.4   d) Normalizing

All leading zeroes of 32-bit integer variable stored in the MD0 .. MD3 registers are removed by shift left operations. The whole operation is completed when the MSB (Most Significant Bit) of MD3 register contains a '1'. After normalizing, bits ARCON.4 (msb) .. ARCON.0 (lsb) contain the number of shift left operations that were done.

18.2.5   e) Shifting

In shift operation, 32-bit integer variable stored in the MD0 ... MD3 registers (the latter contains the most significant byte) is shifted left or right by a specified number of bits. The slr bit (ARCON.5) defines the shift direction and bits ARCON.4 ... ARCON.0 specify the shift count (which must not be 0). During shift operation, zeroes come into the left end of MD3 for shifting right or they come in the right end of the MD0 for shifting left.

18.2.6   f) The mdef flag

The mdef error flag (see) indicates an improperly performed operation (when one of the arithmetic operations is restarted or interrupted by a new operation). The error flag mechanism is automatically enabled with the first write operation to MD0 and disabled with the final read instruction from MD3 (multiplication or shift/norm) or MD5 (division) in phase three.

The error flag is set when:

- If you write to MD0 .. MD5 and/or ARCON during phase two of MDU operation (restart or calculations interrupting).
- If any of the MDx registers are read during phase two of MDU operation when the error flag mechanism is enabled. In this case, the error flag is set but the calculation is not interrupted.

The error flag is reset only after read access to the ARCON register. The error flag is read only.

18.2.7 g) The mdov flag

The mdov overflow flag (see Table 121. on page 146) is set when one of the following conditions occurs:

- division by zero.
- multiplication with a result greater than 0000 FFFFh.
- start of normalizing if the most significant bit of MD3 is set ("md3.7" = '1').

Any operation of the MDU that does not match the above conditions clears the overflow flag.

> **Note:** The overflow flag is exclusively controlled by hardware, it cannot be written.

19 Watchdog and wakeup functions

In order to achieve the lowest possible average current consumption, the processor clock can be stopped under firmware control. Operation can be resumed (wakeup) on external events like toggling of GPIO pins or from the internal RTC wakeup timer, USB or, the RF-module, see chapter 20 on page 154 for details.

In addition, a programmable watchdog timer can be enabled to reset the system if the software hangs.

19.1 Functional description

19.1.1 The Low Frequency Clock (CKLF)

CKLF runs at 32000 Hz (derived from the crystal oscillator) and is used for wakeup functions and the Watchdog.

19.1.2 Tick calibration

The TICK is an interval (in CKLF periods) that determines the resolution of the watchdog and the RTC wakeup timer. The tick is nominally 125 µs (4 CKLF cycles) with a programmable range from 31.25 µs to 8 ms. The TICK is as accurate as the 32 kHz source.

The TICK is controlled by the following SFR:

Addr	Reset value	bit	R/W	Function
0xB5	0x03	7:0	RW	Divider that is used in generating TICK from CKLF frequency. TTICK = (1 + TICK_DV) / fCKLF.

Table 125. TICKDV register

19.1.3 RTC wakeup timer

The RTC is a simple 24 bit down counter that produces an optional interrupt and reloads automatically when the count reaches zero. This process is initially disabled, and is enabled with the first write to the lower 16 bit of the timer latch (WRTCLAT). Writing the lower 16 bits of the timer latch is always followed by a reload of the counter. Only write the upper 8 bit of the timer latch when the timer is disabled, see Table 127. on page 153.

The RTC counter may be disabled again by writing a disable opcode to the control register (WRTCDIS). Both the latch and the counter value may be read by giving the respective codes in the control register, see the description in Table 126. on page 152 and Table 127. on page 153.

The RTC counter is used for a wakeup sometime in the future (a relative time wakeup call). If 'N' is written to the counter, the first wakeup happens between 'N+1' and 'N+2' "TICK" from the completion of the write. From then on a new wakeup is issued every "N+1" "TICK" until the unit is disabled or another value is written to the latch.

The wakeup timer is one of the sources that can generate a WU interrupt (see Table 136. on page 159) to the MCU. You may poll the flag or enable the interrupt. If the MCU is in a power down or standby state, the wakeup forces the device to exit power down or standby regardless of the state of the interrupt enable.

The MCU system does not provide any "absolute time functions". Absolute time functions can be handled in software since the RAM is continuously powered even when in sleep mode.

19.1.4 Programmable GPIO wakeup function

All pins in port 0 can be used as wakeup signals for the MCU system. The device can be programmed to react on rising, falling or, both edges of each pin individually. Additionally, each pin is equipped with a programmable filter that is used for glitch suppression.
Figure 65. Wakeup filter, each pin for GPIO wakeup function

The debounce logic acts as a low pass filter. The input has to be stable for the number of clock pulses that are given (in WGTIMER) to appear on the output. Edge triggers on positive, negative, or both edges. The edge delay is 2 clock cycles. Please see Table 127. on page 153 and Table 128. on page 153 for filter configuration.

19.1.5 Watchdog

The watchdog is activated on the first write to its control register REGXC. It cannot be disabled by any other means than a reset.

The watchdog register is loaded by writing a 16-bit value (number of TICKS) to the two 8-bit data registers (REGXH and REGXL) and then writing the correct opcode to the control register. The watchdog counts down towards 0 and when 0 is reached the complete MCU is reset.

To avoid the reset, the software must regularly load new values into the watchdog register.

19.1.6 Programming interface to watchdog and wakeup functions

Figure 66. on page 152 shows how the blocks that are always active are connected to the MCU.

RTC timer GPIO wakeup and Watchdog are controlled through three SFRs. The three registers, REGXH, REGXL and, REGXC, are used to interface the blocks running on the slow CKLF clock. The 16-bit register REGXH:REGXL can be written or read as two bytes from the MCU.

Typical sequences are:

```
Write:Write REGXH, Write REGXL, Write REGXC
Read: Write REGXC, Read REGXH, Read REGXL
```
Figure 66. Block diagram of wakeup and watchdog functions

describes the functions of the SFR registers that control those blocks, and explains the contents of the individual control registers for watchdog and wakeup functions.

Addr	Reset value	bit	R/W	Init	Name	Function
0xAB	0x00	7:0	RW	0x00	REGXH	Most significant byte of 16-bit data register
0xAC	0x00	7:0	RW	0x00	REGXL	Least significant byte of 16-bit data register
0xAD	0x00	 7:5 4 3 2:0	 - R RW RW	0x00	REGXC	Control register for 16 bit data register Not used Status of last REGXC write access 0: finished, 1: not finished 0: read, 1: write; see R/W column in Table 127. on page 153. Indirect address, see the far left column in Table 127. on page 153.

Table 126. REGXH, REGXL and REGXC registers

Indirect Address	Data register Bit	R/W[a]	Name	Function
000	15:0	R	RWD	Watchdog register (count)
	15:0	W	WWD	Watchdog register (count)
001	15:8	R	RGTIMER	MSB part of RTC counter
	7:0	R		MSB part of RTC latch
	15:12	-	WGTIMER	Not used
	11:8	W		GTIMER latch
	7:0	W		MSB part of RTC latch
010	15:0	R	RRTCLAT	Least significant part of RTC latch
	15:0	W	WRTCLAT	Least significant part of RTC latch
011	15:0	R	RRTC	RTC counter value
	-	W	WRTCDIS	Disable RTC (data not used)

Indirect Address	Data register Bit	R/W[a]	Name	Function
100	15:9	-	RWSTA0	Not used
	8	R		RTC timer status
	5:0	R		Wakeup status for pins P05-P00
100	15:14	W	WWCON0	Edge selection of P03
	13:12	W		Debounce filter for P03
	11:10	W		Edge selection of P02
	9:8	W		Debounce filter for P02
	7:6	W		Edge selection of P01
	5:4	W		Debounce filter for P01
	3:2	W		Edge selection of P00
	1:0	W		Debounce filter for P00, see Table 128. on page 153.
101	15:9	-	RWSTA1	Not used
	8	R		RTC timer status
	7:0	R		Wakeup status for pins P05-P00
	15:8	-	WWCON1	Not used
	7:6	W		Edge selection of P05
	5:4	W		Debounce filter for P05
	3:2	W		Edge selection of P04
	1:0	W		Debounce filter for P04, see Table 128. on page 153.
110	15:0	-	-	Reserved, do not use
111	15:0	-	-	Reserved, do not use

a. REGXC bit-3 selects between R(ead) and W(rite) operation

Table 127. Indirect addresses and functions

Debounce filter selection		Edge selection	
Code	Number of clock pulses	Code	positive/negative trigger
00	0	00	Off
01	2	01	Positive
10	8	10	Negative
11	64	11	Both

Table 128. GPIO wakeup filter configuration, WWCON

20   Power management

The nRF24LU1 Power Management function controls the power dissipation through the administration of modes of operation and by controlling clock frequencies.

20.1   Modes of operation

There are four main power consuming functions on the chip. These can be controlled on and off in different ways depending on the required functionality after the start-up/reset sequence is ended.

These functions are:

- MCU
    ▸ states of operation: active and standby
    ▸ active at the end of the reset sequence
    ▸ Set to standby by software (write `PWRDWN` register = 0x01)
    ▸ Set to active by wakeup sources:
      Interrupt from USB
      Interrupt from RF Transceiver
      Interrupt from external pin
      Interrupt from on-chip RTC

- RF Transceiver
    ▸ states of operation: **power down**, **standby** and **active** (TX or RX)
    ▸ pwrdwn at the end of the reset sequence
    ▸ Set to **standby**, **active** or **power down** by software, see section 6.3.1 on page 27

- USB
    ▸ states of operation: active and suspend
    ▸ active at the end of the reset sequence
    ▸ Set to suspend by software (write USBSLP register = 0x01)
    ▸ Set to active by software or by wakeup from USB host (through the USB bus)

- PLL
    ▸ states of operation: on and off
    ▸ on at the end of the reset sequence
    ▸ Set to on or off by hardware with one exception:
      if the USB is in suspend the PLL may be controlled by software
      (Enable PLL, bit 7 in the CLKCTL register)

Table 129. on page 155 summarizes the available modes of operation after the reset sequence is ended:

- `PROG` is an external pin on the nRF24LU1.
- RF Transceiver, USB, MCU and PLL represent the functions defined above.

PROG	RF Transceiver	USB	MCU	PLL	Comment
1	-	-	-	-	Flash programming mode via SPI
0	standby	suspend	standby	OFF	
0	standby	suspend	active	software	
0	standby	active	standby	ON	
0	standby	active	active	ON	
0	active	suspend	standby	OFF	
0	active	suspend	active	software	
0	active	active	standby	ON	
0	active	active	active	ON	

Table 129. nRF24LU1 modes of operation

In nRF24LU1 the 16 MHz oscillator is always running. An internal PLL can be enabled that multiplies the 16 MHz by three to get an internal 48 MHz clock. This clock is required for USB operation.

The internal 32.000 kHz clock (CKLF) is generated from the 16/48 MHz source.

To save power when the USB is suspended, the PLL can be turned off, and the clock frequency to the MCU can be reduced. This reduces power consumption, but also reduces performance.

To further reduce power, the MCU clock can be stopped using the PWRDWN register. In the PCON register stop and idle modes can be selected, but since their effect on power consumption is minor use PWRDWN.

The following various internal and external events can resume the MCU clock:

- Interrupt from RF Transceiver, rfirq
- Interrupt from USB
- Interrupt from RTC timer or GPIO-pins (see chapter 19 on page 150)

The WUCONF register controls how these events are handled.

20.2 Functional description

20.2.1 Clock control – CLKCTL

Addr	Reset value	Bit	R/W	Function
0xA3	0x80	7	RW	Enable PLL, 1: PLL on, 0: PLL off
		6:4	RW	Set Cclk (MCU clock) frequency when PLL is ON 000: 16MHz 001: 12MHz 010: 8MHz 011: 4MHz 100: 1.6MHz Other combinations: reserved.
		3:2	-	Not used
		1:0	RW	Set Cclk (MCU clock) frequency when PLL is OFF 00: 4 MHz 01: 1.6 MHz 10: 320 kHz 11: 64 kHz Other combinations: reserved.

Table 130. CLKCTL register

20.2.2 Power down control – PWRDWN

Addr	Reset value	Bit	R/W	Function
0xA4	0x00	7:4	-	Not used
		3	R	Read CKLF clock (32 kHz clock, always running)
		2:0	W	Set MCU to standby if different from 000

Note: Any pending interrupt must be cleared before setting MCU to standby.

Table 131.PWRDWN register

20.2.3 Reset result – RSTRES

The following three reset sources initiate the same reset/start-up sequence:

- Reset from the on-chip reset generator.
- Reset from pin.
- Reset generated from the on-chip watchdog function.

The RSTRES register stores the reset cause:

Addr	Reset value	Bit	R/W	Function
0xB1	0x00	7:1	-	Not used
		0	R	Reset cause, 1: Watchdog, 0: other

Table 132. RSTRES register

20.2.4 Wakeup configuration register – WUCONF

Addr	Reset value	Bit	R/W	Function
0xA5	0x00	7:6	RW	00: Enable wakeup on RFIRQ, if IEN1.1=1 01: Reserved, not used 10: Enable wakeup on RFIRQ, regardless of IEN1.1 11: Ignore RFIRQ
		5:4	RW	00: Enable wakeup on WU, if IEN1.5=1[a] 01: Reserved, not used 10: Enable wakeup on WU, regardless of IEN1.5 11: Ignore WU
		3:2	RW	00: Enable wakeup on USBIRQ, if IEN1.4=1 01: Reserved, not used 10: Enable wakeup on USBIRQ, regardless of IEN1.4 11: Ignore USBIRQ
		1:0	RW	00: Enable wakeup on USBWU, if IEN1.3=1 01: Reserved, not used 10: Enable wakeup on USBWU, regardless of IEN1.3 11: Ignore USBWU

a. WU is generated as described in sections 19.1.3 and 19.1.4

Table 133. WUCONF register

20.2.5 Power control register - PCON

The PCON register is used to control the Power Down Modes (IDLE, STOP), the Program Memory Write Mode and Serial Port 0 baud rate doubler.

Address	Reset value	Bit	Name	Description
0x87	0x00	7	smod	Serial Port 0 baud rate select, see Table 87. on page 108 (baud rate doubler).
		6	gf3	General purpose flag 3
		5	gf2	General purpose flag 2
		4	pmw	Program memory write mode. Setting this bit enables the program memory write mode.
		3	gf1	General purpose flag 1
		2	gf0	General purpose flag 0
		1	stop	Stop mode control. Setting this bit activates the Stop Mode. Always read as 0.
		0	idle	Idle mode control. Setting this bit activates the Idle Mode. Always read as 0.

Table 134. PCON register

21 Interrupts

nRF24LU1 has an advanced interrupt controller with 15 sources, as shown in Figure 67..
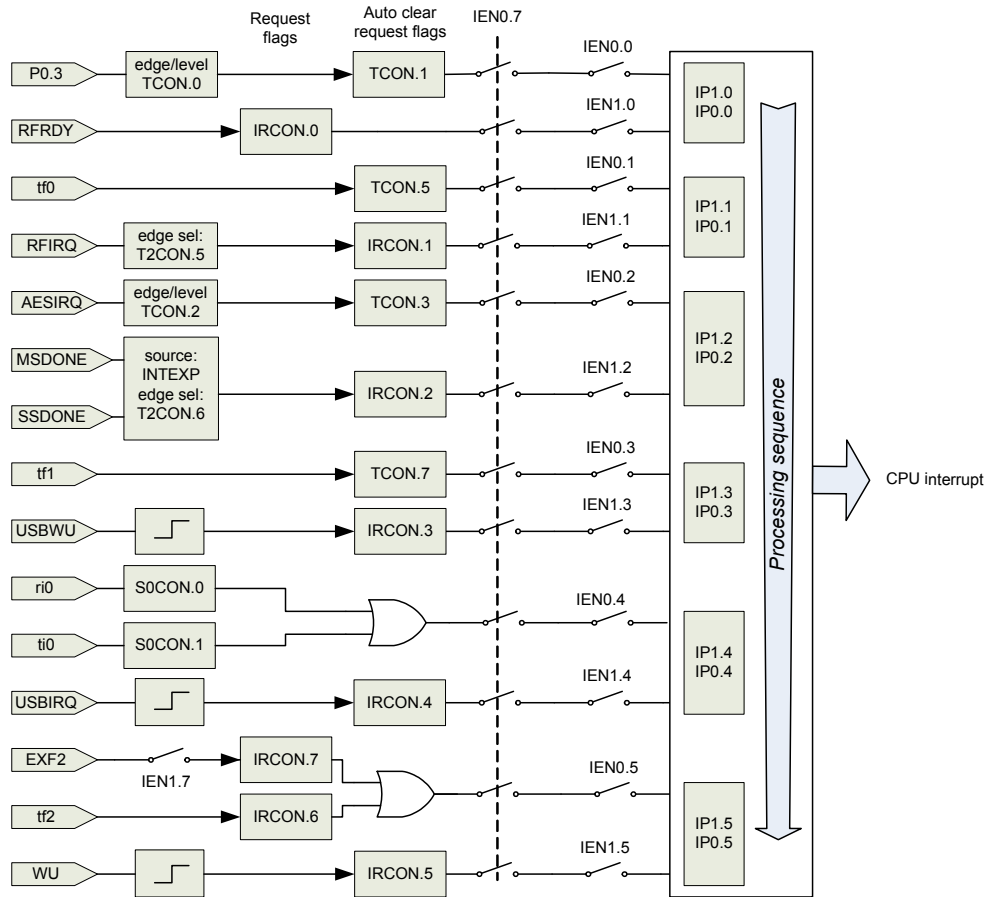

Figure 67. nRF24LU1 interrupt structure

21.1 Features

When an enabled interrupt occurs, the MCU vectors to the address of the interrupt service routine (ISR) associated with that interrupt, as listed in Table 135. on page 159. The MCU executes the ISR to completion unless another interrupt of higher priority occurs.

Source	Vector	Polarity	Description
P0.3	0x0003	low/fall	External pin P0.3
tf0	0x000B	high	Timer 0 interrupt
AESIRQ	0x0013	low/fall	AES ready interrupt
tf1	0x001B	high	Timer 1 interrupt
ri0	0x0023	high	Serial channel receive interrupt
ti0	0x0023	high	Serial channel transmit interrupt
tf2	0x002B	high	Timer 2 interrupt
EXF2	0x002B	High	Timer 2 external event (pin P0.5)
RFRDY	0x0043	high	RF SPI ready

Source	Vector	Polarity	Description
RFIRQ	0x004B	fall/rise	RF IRQ
MSDONE	0x0053	fall/rise	Master SPI transaction completed
SSDONE	0x0053	fall/rise	Slave SPI transaction completed
USBWU	0x005B	rise	USB wakeup interrupt
USBIRQ	0x0063	rise	USB interrupt
WU	0x006B	rise	Internal Wakeup interrupt

Table 135. nRF24LU1 interrupt sources

21.2 Functional description

Various SFR registers are used to control and prioritize between different interrupts.

The IRCON, SCON, IP0, IP1, IEN0, IEN1 and INTEXP are described in this section. In addition, a description of the TCON and T2CON registers is found in chapter 11 on page 100.

21.2.1 Interrupt enable 0 register – IEN0

The IEN0 register is responsible for global interrupt system enabling/disabling as well as Timer0, 1 and 2, Port 0 and Serial Port individual interrupts enabling/disabling.

Address	Reset value	Bit	Description
0xA8	0x00	7	1: Enable interrupts. 0: all interrupts are disabled.
		6	Not used.
		5	1: Enable Timer2 interrupt.
		4	1: Enable Serial Port interrupt.
		3	1: Enable Timer1 overflow interrupt
		2	1: Enable pin P0.4 interrupt.
		1	1: Enable Timer0 overflow interrupt.
		0	1: Enable pin P0.3 interrupt.

Table 136. IEN0 register

21.2.2 Interrupt enable 1 register – IEN1

The IEN1 register is responsible for RF, SPI, USB and Timer 2 interrupts.

Address	Reset value	Bit	Description
0xB8	0x00	7	1: Enable Timer2 external reload interrupt
		6	Not used
		5	1: Wakeup interrupt enable
		4	1: USB interrupt enable
		3	1: USB wakeup interrupt enable
		2	1: Master or Slave SPI ready interrupt enable
		1	1: RF interrupt enable
		0	1: RF SPI ready enable

Table 137. IEN1 register

Master SPI and Slave SPI share the same interrupt line.

Address	Reset value	Bit	Function
0xA6	0x01	7:2	Not used
		1	1: Enable Master SPI interrupt
		0	1: Enable Slave SPI interrupt

Table 138. INTEXP register.

21.2.3   Interrupt priority registers – IP0, IP1

The 14 interrupt sources are grouped into six priority groups. For each of the groups, one of four priority levels can be selected. It is achieved by setting appropriate values in IP0 and IP1 registers.

The contents of the Interrupt Priority Registers define the priority levels for each interrupt source according to the tables below.

Address	Reset value	Bit	Description
0xA9	0x00	7:6	Not used.
		5:0	Interrupt priority. Each bit together with corresponding bit from IP1 register specifies the priority level of the respective interrupt priority group.

Table 139. IP0 register

Address	Reset value	Bit	Description
0xB9	0x00	7:6	Not used.
		5:0	Interrupt priority. Each bit together with corresponding bit from IP0 register specifies the priority level of the respective interrupt priority group.

Table 140. IP1 register

Group	Interrupt bits	Priority groups		
0	ip1.0, ip0.0	P0.3 interrupt	RF interrupt	
1	ip1.1, ip0.1	Timer 0 interrupt	RF SPI interrupt	
2	ip1.2, ip0.2	P0.4 interrupt	Master SPI	Slave SPI
3	ip1.3, ip0.3	Timer 1 interrupt	USB wakeup	
4	ip1.4, ip0.4	Serial port receive	Serial port transmit	USB interrupt
5	ip1.5, ip0.5	Timer 2 interrupt	Wakeup interrupt	

Table 141. Priority groups

ip1.x	ip0.x	Priority level
0	0	Level 0 (lowest)
0	1	Level 1
1	0	Level 2
1	1	Level 3 (highest)

Table 142. Priority levels (x is the number of priority group)

21.2.4 Interrupt request control registers – IRCON

The IRCON register contains Timer 2, SPI, RF, USB and wakeup interrupt request flags.

Address	Reset value	Bit	Auto clear	Description
0xC0	0x00	7	-	Timer 2 external reload flag
		6	-	Timer 2 overflow flag
		5	Yes	Wakeup interrupt flag
		4	Yes	USB interrupt flag
		3	Yes	USB wakeup interrupt flag
		2	Yes	Master or Slave SPI interrupt flag
		1	Yes	RF interrupt flag
		0	-	RF SPI interrupt flag

Table 143. IRCON register

22   HW debugger support

The nRF24LU1 has the following on-chip hardware debug support for the JTAG debugger:

- System Navigator from First Silicon Solutions (www.fs2.com).

This debugger connects to the nRF24LU1 through four wires, and to a PC through USB. With this interface all internal operations (memory, registers, IO) are visible on the PC screen and can be controlled from the PC.

22.1   Features

- Read/write all processor registers, SFR, program and data memory.
- Go/halt processor run control.
- Single step by assembly and C source instruction.
- Unlimited software breakpoints (for programs in RAM).
- Load binary, Intel Hex or OMF51 file formats.
- Two independent HW execution breakpoints (complex triggers). These can be paired for range setting.
- Complex triggers monitor address and data for code memory, data memory and SFRs.
- Driver software for Keil µVision debugger interface.
- Measure time in nanoseconds between triggers.
- Low-level access to JTAG functions for silicon verification.
- Real time trace, branch history stored in on-chip 128 deep branch trace history buffer. Effective trace-length larger since only effective branches are saved.
- Single line assembler and disassembler.
- Trace window with full trace decode into instruction mnemonics.
- Symbolic debug.
- Load symbols, including code, variables and variable types.
- Support C and assembly source code.
- Source window can display C source and mixed mode.
- Source window provides execution control; go, halt; goto cursor; step over/into call.
- Source window can set or clear software and hardware breakpoints.
- Trigger window for setting complex triggers.

22.2   Functional description

The debug interface is enabled by writing (through the SPI) to address 0x24 in the infopage. Any byte value other than 0xFF enables debug. The Flash Status Register (FSR bit 7, table 20) shows the current status of the interface. In debug mode the four GPIO lines P0.0-P0.3 are configured for JTAG operation and cannot be used for other purposes.

The JTAG interface signals are mapped out on the GPIO lines and must be connected to the System Navigator cable. The mapping is:TDI=P0.2, TDO=P0.3, TCK=P0.0, TMS=P0.1.

> **Note:** A pull-up on P0.0 is required for the MCU to run (in debug mode) without the system navigator cable plugged in.

A separate TRIG_OUT is available on the P0.4 pin. This output can be activated when certain address and data-combinations occur.

23 Peripheral information

This chapter describes peripheral circuitry and PCB layout requirements that are important for achieving optimum RF performance from the nRF24LU1.

23.1 Antenna output

The ANT1 and ANT2 output pins provide a balanced RF output to the antenna. The pins must have a DC path to VDD_PA, either through a RF choke or through the center point in a balanced dipole antenna. A load of 15 W+j88 W is recommended for maximum output power (0dBm). Lower load impedance (for instance 50 W) can be obtained by fitting a simple matching network between the load and ANT1 and ANT2. A recommended matching network for 50W load impedance is illustrated in Chapter 24 on page 165.

23.2 Crystal oscillator

A crystal being used with the nRF24LU1 must fulfil the specifications given in Table 9. on page 24.

You must use a crystal with a low load capacitance specification to achieve a crystal oscillator solution with low power consumption and fast start-up time. A lower C0 also gives lower current consumption and faster start-up time, but may increase the cost of the crystal. Typically C0=1.5pF at a crystal specified for C0max=7.0pF.

The crystal load capacitance, CL, is given by:

$$C_L = \frac{C_1' \cdot C_2'}{C_1' + C_2'}$$, where C1' = C1 + CPCB1 + CI1 and C2' = C2 + CPCB2 + CI2

C1 and C2 are SMD capacitors as shown in the application schematics, see Chapter 24 on page 165. CPCB1 and CPCB2 are the layout parasitic on the circuit board. CI1 and CI2 are the capacitance seen into the XC1 and XC2 pins respectively; the value is typically 1pF for each of these pins.

23.3 PCB layout and decoupling guidelines

A well designed PCB is necessary to achieve good RF performance. A poor layout can lead to loss of performance or functionality. A fully qualified RF-layout for the nRF24LU1 and its surrounding components, including matching networks, can be downloaded from www.nordicsemi.no.

A PCB with a minimum of two layers including a ground plane is recommended for optimum performance. The nRF24LU1 DC supply voltage should be decoupled as close as possible to the VDD pins with high performance RF capacitors.See the schematics layout in Chapter 24 on page 165 for recommended decoupling capacitor values. The nRF24LU1 supply voltage should be filtered and routed separately from the supply voltages of any digital circuitry.

Long power supply lines on the PCB should be avoided. All device grounds, VDD connections and VDD bypass capacitors must be connected as close as possible to the nRF24LU1 IC. For a PCB with a topside RF ground plane, the VSS pins should be connected directly to the ground plane. For a PCB with a bottom ground plane, the best technique is to have via holes as close as possible to the VSS pads. A minimum of one via hole should be used for each VSS pin.

Full swing digital data or control signals should not be routed close to the crystal or the power supply lines. The exposed die attach pad is a ground pad connected to the IC substrate die ground and is intentionally not used in our layouts. It is recommended to keep it unconnected.

24 Application example

24.1 Schematics
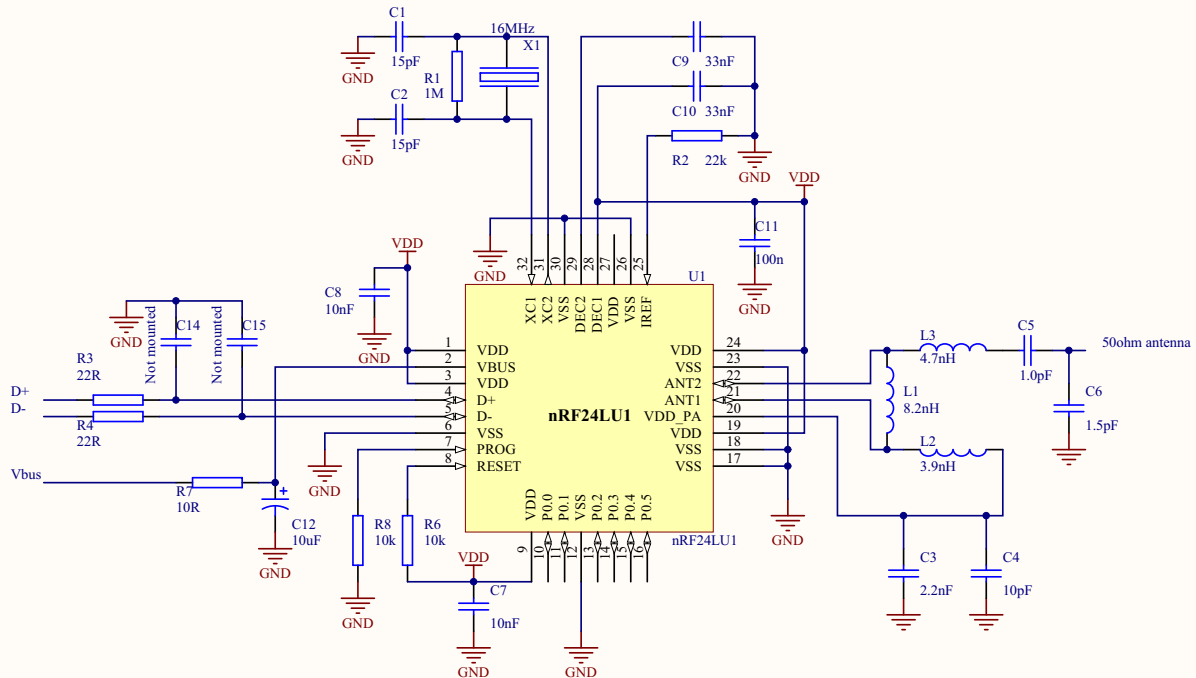

24.2 Layout

A double sided FR-4 board of 1.6 mm thickness is used. This PCB has a ground plane on the bottom layer. There are ground areas on the component side of the board to ensure sufficient grounding of critical components. A large number of via holes connect the top layer to ground areas to the bottom layer ground plane.

Table 149. Glossary

Appendix A - (USB memory configurations)

The USB buffer memory has a total size of 512 bytes. Bulk/control buffer size can be 2, 4, 8, 16, 32 or, 64 bytes, while ISO buffers (if used) must be multiples of 16 bytes.

Some example configurations are given below.

Configuration 1

Endpoint 0-5 Bulk/control IN/OUT, each of size 32 bytes.

Endpoint 8 ISO IN/OUT, each of size 32 bytes (with double buffering).

Total buffer area: 448 bytes.

Register	Value (hex)	Calculation	Comment
bout1addr	0x10	(ep0 size)/2	Start addr. of bulk 1 OUT
bout2addr	0x20	bout1addr + (ep1 size)/2	Start addr. of bulk 2 OUT
bout3addr	0x30	bout2addr + (ep2 out size)/2	Start addr. of bulk 3 OUT
bout4addr	0x40	bout3addr + (ep3 size)/2	Start addr. of bulk 4 OUT
bout5addr	0x50	bout4addr + (ep4 out size)/2	Start addr. of bulk 5 OUT
binstaddr	0x30	(bulk out size)/4	Start addr. of bulk 1 IN
bin1addr	0x10	(ep0 in size)/2	Start addr. of bulk 1 IN
bin2addr	0x20	bin1addr + (ep1 in size)/2	Start addr. of bulk 2 IN
bin3addr	0x30	bin2addr + (ep2 in size)/2	Start addr. of bulk 3 IN
bin4addr	0x40	bin3addr + (ep3 in size)/2	Start addr. of bulk 4 IN
bin5addr	0x50	bin4addr + (ep4 in size)/2	Start addr. of bulk 5 IN
isostaddr	0x18	(bulk size)/16	Start addr. of iso
out8addr	0x00	0	Start addr. of iso OUT
in8addr	0x04	(ep4 out size)/4	Start addr. of iso IN
isosize	0x02	(iso size)/16	

Table 150. Configuration 1

Configuration 2

Endpoint 0-2 bulk/control IN/OUT, each of size 32 bytes

Endpoint 3-4 bulk IN/OUT, each of size 16 bytes

Endpoint 8 ISO IN/OUT, each of size 32 bytes (with double buffering).

Total buffer area: 320 bytes

Register	value (hex)	Calculation	Comment
bout1addr	0x10	(ep0 out size)/2	Start addr. of bulk 1 OUT
bout2addr	0x20	bout1addr + (ep1 out size)/2	Start addr. of bulk 2 OUT

Table 153. Configuration 4

Appendix B - Configuration for compatibility with nRF24XX

How to setup the radio module in nRF24LU1 to receive from an nRF2401/nRF2402/nRF24E1/nRF24E2:

1. Use the same CRC configuration as the nRF2401/nRF2402/nRF24E1/nRF24E2.
2. Set the PWR_UP and PRIM_RX bit to 1.
3. Disable auto acknowledgement on the addressed data pipe.
4. Use the same address width as the PTX device.
5. Use the same frequency channel as the PTX device.
6. Select data rate 1Mbps on both nRF24LU1 and nRF2401/nRF2402/nRF24E1/nRF24E2.
7. Set correct payload width on the addressed data pipe.
8. Set rfce high.

How to setup the radio module in nRF24LU1 to transmit to an nRF2401/nRF24E1:

1. Use the same CRC configuration as the nRF2401/nRF24E1.
2. Set the PRIM_RX bit to 0.
3. Set the Auto Retransmit Count to 0 to disable the auto retransmit functionality.
4. Use the same address width as the nRF2401/nRF24E1.
5. Use the same frequency channel as the nRF2401/nRF24E1.
6. Select data rate 1Mbps on both nRF24LU1 and nRF2401/nRF24E1.
7. Set PWR_UP high.
8. Clock in a payload that has the same length as the nRF2401/nRF24E1 is configured to receive.
9. Pulse rfce to transmit the packet.
